# Package 'flexclust'

February 28, 2025

Version 1.5.0
<b>Date</b> 2025-02-27
Encoding UTF-8
Title Flexible Cluster Algorithms
<b>Depends</b> R (>= 2.14.0)
<b>Imports</b> graphics, grid, lattice, methods, modeltools, parallel, stats, stats4, class
Suggests ellipse, clue, cluster, seriation, skmeans
<b>Description</b> The main function kcca implements a general framework for k-centroids cluster analysis supporting arbitrary distance measures and centroid computation. Further cluster methods include hard competitive learning, neural gas, and QT clustering. There are numerous visualization methods for cluster results (neighborhood graphs, convex cluster hulls, barcharts of centroids,), and bootstrap methods for the analysis of cluster stability.

Achievement Test Scores for New Haven Schools

## **Description**

Measurements at the beginning of the 4th grade (when the national average is 4.0) and of the 6th grade in 25 schools in New Haven.

# Usage

```
data(achieve)
```

#### **Format**

A data frame with 25 observations on the following 4 variables.

```
read4 4th grade reading.
arith4 4th grade arithmetic.
```

10 61 1 1

read6 6th grade reading.

arith6 6th grade arithmetic.

#### References

auto

Automobile Customer Survey Data

## **Description**

A German manufacturer of premium cars asked customers approximately 3 months after a car purchase which characteristics of the car were most important for the decision to buy the car. The survey was done in 1983 and the data set contains all responses without missing values.

#### Usage

data(auto)

4 auto

#### **Format**

A data frame with 793 observations on the following 46 variables.

model A factor with levels A, B, C, or D; model bought by the customer.

gear A factor with levels 4 gears, 5 econo, 5 sport, or automatic.

leasing A logical vector, was leasing used to finance the car?

usage A factor with levels private, both, business.

previous\_model A factor describing which type of car was owned directly before the purchase.

other\_consider A factor with levels same manuf, other manuf, both, or none.

test\_drive A logical vector, did you do a test drive?

info\_adv A logical vector, was advertising an important source of information?

info\_exp A logical vector, was experience an important source of information?

info\_rec A logical vector, were recommendations an important source of information?

ch\_clarity A logical vector.

ch\_economy A logical vector.

ch\_driving\_properties A logical vector.

ch\_service A logical vector.

ch\_interior A logical vector.

ch\_quality A logical vector.

ch\_technology A logical vector.

ch\_model\_continuity A logical vector.

ch\_comfort A logical vector.

ch\_reliability A logical vector.

ch\_handling A logical vector.

ch\_reputation A logical vector.

ch\_concept A logical vector.

ch\_character A logical vector.

ch\_power A logical vector.

ch\_resale\_value A logical vector.

ch\_styling A logical vector.

ch\_safety A logical vector.

ch\_sporty A logical vector.

ch\_consumption A logical vector.

ch\_space A logical vector.

satisfaction A numeric vector describing overall satisfaction (1=very good, 10=very bad).

good1 Conception, styling, dimensions.

good2 Auto body.

good3 Driving and coupled axles.

barplot-methods 5

```
good4 Engine.
good5 Electronics.
good6 Financing and customer service.
good7 Other.
sporty What do you think about the balance of sportiness and comfort? (good, more sport, more comfort).
drive_char Driving characteristis (gentle < speedy < powerfull < extreme).
tempo Which average speed do you prefer on German Autobahn in km/h? (< 130 < 130-150 < 150-180 <> 180)
consumption An ordered factor with levels low < ok < high < too high.
gender A factor with levels male and female
occupation A factor with levels self-employed, freelance, and employee.
household Size of household, an ordered factor with levels 1-2 <>=3.
```

#### **Source**

The original German data are in the public domain and available from LMU Munich (doi:10.5282/ubm/data.14). The variable names and help page were translated to English and converted into Rd format by Friedrich Leisch.

#### References

summary(auto)
```

barplot-methods

Barplot/chart Methods in Package 'flexclust'

#### **Description**

Barplot of cluster centers or other cluster statistics.

# Usage

```
## S4 method for signature 'kcca'
barplot(height, bycluster = TRUE, oneplot = TRUE,
    data = NULL, FUN = colMeans, main = deparse(substitute(height)),
    which = 1:height@k, names.arg = NULL,
    oma = par("oma"), col = NULL, mcol = "darkred", srt = 45, ...)
## S4 method for signature 'kcca'
```

6 barplot-methods

```
barchart(x, data, xlab="", strip.labels=NULL,
    strip.prefix="Cluster ", col=NULL, mcol="darkred", mlcol=mcol,
    which=NULL, legend=FALSE, shade=FALSE, diff=NULL, byvar=FALSE,
    clusters=1:x@k, ...)
## S4 method for signature 'hclust'
barchart(x, data, xlab="", strip.labels=NULL,
    strip.prefix="Cluster ", col=NULL, mcol="darkred", mlcol=mcol,
    which=NULL, shade=FALSE, diff=NULL, byvar=FALSE, k=2, ...)
## S4 method for signature 'bclust'
barchart(x, data, xlab="", strip.labels=NULL,
    strip.prefix="Cluster ", col=NULL, mcol="darkred", mlcol=mcol,
    which=NULL, legend=FALSE, shade=FALSE, diff=NULL, byvar=FALSE,
    k=x@k, clusters=1:k, ...)
```

#### **Arguments**

height, x An object of class "kcca".

bycluster If TRUE, then each barplot shows one cluster. If FALSE, then each barplot com-

pares all cluster for one input variable.

oneplot If TRUE, all barplots are plotted together on one page, else each plot is on a

separate page.

data If not NULL, cluster membership is predicted for the new data and used for the

plots. By default the values from the training data are used. Ignored by the

barchart method.

FUN The function to be applied to each cluster for calculating the bar heights. Only

used, if data is not NULL.

which For barplot index number of clusters for the plot, for barchart index numbers

or names of variables to plot.

names.arg A vector of names to be plotted below each bar.

main, oma, xlab, ...

Graphical parameters.

col Vector of colors for the clusters.

mcol, mlcol If not NULL, the value of FUN for the complete data set is plotted over each bar as

a point with color mcol and a line segment starting in zero with color mlcol.

srt Number between 0 and 90, rotation of the x-axis labels.

strip.labels Vector of strings for the strips of the Trellis display.

strip.prefix Prefix string for the strips of the Trellis display.

legend If TRUE, the barchart is always plotted on the current graphics device and a leg-

end is added to the bottom of the plot.

shade If TRUE, only bars with large absolute or relative deviation deviation from the

sample mean of the respective variables are plotted in color.

diff A numerical vector of length two with absolute and relative deviations for shad-

ing, default is max/4 absolute deviation and 50% relative deviation.

barplot-methods 7

byvar If TRUE, a panel is plotted for each variable. By default a panel is plotted for

each cluster.

clusters Integer vector of clusters to plot.

k Integer specifying the desired number of clusters.

#### Note

The flexclust barchart method uses a horizontal arrangements of the bars, and sorts them from top to bottom. Default barcharts in lattice are the other way round (bottom to top). See the examples below how this affects, e.g., manual labels for the y axis.

The barplot method is legacy code and only maintained to keep up with changes in R, all active development is done on barchart.

```
cl <- cclust(iris[,-5], k=3)</pre>
barplot(cl)
barplot(cl, bycluster=FALSE)
## plot the maximum instead of mean value per cluster:
barplot(cl, bycluster=FALSE, data=iris[,-5],
        FUN=function(x) apply(x,2,max))
## use lattice for plotting:
barchart(cl)
## automatic abbreviation of labels
barchart(cl, scales=list(abbreviate=TRUE))
## origin of bars at zero
barchart(cl, scales=list(abbreviate=TRUE), origin=0)
## Use manual labels. Note that the flexclust barchart orders bars
## from top to bottom (the default does it the other way round), hence
## we have to rev() the labels:
LAB <- c("SL", "SW", "PL", "PW")
barchart(cl, scales=list(y=list(labels=rev(LAB))), origin=0)
## deviation of each cluster center from the population means
barchart(cl, origin=rev(cl@xcent), mlcol=NULL)
## use shading to highlight large deviations from population mean
barchart(cl, shade=TRUE)
```

8 bclust

```
## use smaller deviation limit than default and add a legend
barchart(cl, shade=TRUE, diff=0.2, legend=TRUE)
```

bclust

Bagged Clustering

## **Description**

Cluster the data in x using the bagged clustering algorithm. A partitioning cluster algorithm such as cclust is run repeatedly on bootstrap samples from the original data. The resulting cluster centers are then combined using the hierarchical cluster algorithm hclust.

## Usage

#### Arguments

Х	Matrix of inputs (or object of class "bclust" for plot).
k	Number of clusters.
base.iter	Number of runs of the base cluster algorithm.
base.k	Number of centers used in each repetition of the base method.
minsize	Minimum number of points in a base cluster.
dist.method	Distance method used for the hierarchical clustering, see dist for available distances.
hclust.method	Linkage method used for the hierarchical clustering, see hclust for available methods.
FUN	Partitioning cluster method used as base algorithm.
verbose	Output status messages.
final.cclust	If TRUE, a final cclust step is performed using the output of the bagged clustering as initialization.
resample	Logical, if TRUE the base method is run on bootstrap samples of $x$ , else directly on $x$ .
weights	Vector of length $nrow(x)$ , weights for the resampling. By default all observations have equal weight.

belust 9

maxcluster Maximum number of clusters memberships are to be computed for.

object Object of class "bclust".

main Main title of the plot.

.. Optional arguments top be passed to the base method in bclust, ignored in

plot.

y Missing.

newdata An optional data matrix with the same number of columns as the cluster centers.

If omitted, the fitted values are used.

#### **Details**

First, base.iter bootstrap samples of the original data in x are created by drawing with replacement. The base cluster method is run on each of these samples with base.k centers. The base.method must be the name of a partitioning cluster function returning an object with the same slots as the return value of cclust.

This results in a collection of iter.base \* base.centers centers, which are subsequently clustered using the hierarchical method hclust. Base centers with less than minsize points in there respective partitions are removed before the hierarchical clustering. The resulting dendrogram is then cut to produce k clusters.

#### Value

bclust returns objects of class "bclust" including the slots

hclust Return value of the hierarchical clustering of the collection of base centers (Ob-

ject of class "hclust").

cluster Vector with indices of the clusters the inputs are assigned to.

centers Matrix of centers of the final clusters. Only useful, if the hierarchical clustering

method produces convex clusters.

allcenters Matrix of all iter.base \* base.centers centers found in the base runs.

birth

Birth and Death Rates

## **Description**

Birth and death rates for 70 countries.

## Usage

```
data(birth)
```

#### **Format**

A data frame with 70 observations on the following 2 variables.

```
birth Birth rate (in percent).
death Death rate (in percent).
```

bootFlexclust

Bootstrap Flexclust Algorithms

# Description

Runs clustering algorithms repeatedly for different numbers of clusters on bootstrap replica of the original data and returns corresponding cluster assignments, centroids and (adjusted) Rand indices comparing pairs of partitions.

bootFlexclust 11

## Usage

## **Arguments**

x, k,	Passed to stepFlexclust.
nboot	Number of bootstrap pairs of partitions.
correct	Logical, correct the Rand index for agreement by chance also called adjusted Rand index)?
seed	If not NULL, a call to set.seed() is made before any clustering is done.
multicore	If TRUE, use package <b>parallel</b> for parallel processing. In addition, it may be a workstation cluster object as returned by makeCluster, see examples below.
verbose	If TRUE, show progress information during computations. Will not work with $\mbox{multicore=TRUE}$ .
y, data	Not used.
object	An object of class "bootFlexclust".

#### **Details**

Availability of **multicore** is checked when **flexclust** is loaded. This information is stored and can be obtained using getOption("flexclust")\$have\_multicore. Set to FALSE for debugging and more sensible error messages in case something goes wrong.

bundestag

German Parliament Election Data

## **Description**

Results of the elections 2002, 2005 or 2009 for the German Bundestag, the first chamber of the German parliament.

#### Usage

```
data(btw2002)
data(btw2005)
data(btw2009)
bundestag(year, second=TRUE, percent=TRUE, nazero=TRUE, state=FALSE)
```

Numeric or character, year of the election.

#### **Arguments**

year

second	Logical, return second or first votes?
percent	Logical, return percentages or absolute numbers?
nazero	Logical, convert NAs to 0?
state	Logical or character. If TRUE then only column state from the corresponding data frame is returned, and all other arguments are ignored. If character, then it

is used as pattern to grep for the corresponding state(s), see examples.

bundestag 13

#### **Format**

btw200x are data frames with 299 rows (corresponding to constituencies) and 17 columns. All columns except state are numeric.

state Factor, the 16 German federal states.

eligible Number of citizens eligible to vote.

votes Number of eligible citizens who did vote.

invalid1, invalid2 Number of invalid first and second votes (see details below).

valid1, valid2 Number of valid first and second votes.

SPD1, SPD2 Number of first and second votes for the Social Democrats.

UNION1, UNION2 Number of first and second votes for CDU/CSU, the conservative Christian Democrats.

GRUENE1, GRUENE2 Number of first and second votes for the Green Party.

FDP1, FDP2 Number of first and second votes for the Liberal Party.

LINKE1, LINKE2 Number of first and second votes for the Left Party (PDS in 2002).

Missing values indicate that a party did not candidate in the corresponding constituency.

#### **Details**

btw200x are the original data sets. bundestag() is a helper function which extracts first or second votes, calculates percentages (number of votes for a party divided by number of valid votes), replaces missing values by zero, and converts the result from a data frame to a matrix. By default it returns the percentage of second votes for each party, which determines the number of seats each party gets in parliament.

#### **German Federal Elections**

Half of the Members of the German Bundestag are elected directly from Germany's 299 constituencies, the other half on the parties' state lists. Accordingly, each voter has two votes in the elections to the German Bundestag. The first vote, allowing voters to elect their local representatives to the Bundestag, decides which candidates are sent to Parliament from the constituencies.

The second vote is cast for a party list. And it is this second vote that determines the relative strengths of the parties represented in the Bundestag. At least 598 Members of the German Bundestag are elected in this way. In addition to this, there are certain circumstances in which some candidates win what are known as "overhang mandates" when the seats are being distributed.

bwplot-methods

Box-Whisker Plot Methods in Package 'flexclust'

#### **Description**

Seperate boxplot of variables in each cluster in comparison with boxplot for complete sample.

#### Usage

```
## S4 method for signature 'kcca'
bwplot(x, data, xlab="",
       strip.labels=NULL, strip.prefix="Cluster",
       col=NULL, shade=!is.null(shadefun), shadefun=NULL, byvar=FALSE, ...)
## S4 method for signature 'bclust'
bwplot(x, k=x@k, xlab="", strip.labels=NULL,
       strip.prefix="Cluster", clusters=1:k, ...)
```

#### **Arguments**

X	An object	of class	"kcca"	or "bo	clust".

data If not NULL, cluster membership is predicted for the new data and used for the

plots. By default the values from the training data are used.

Graphical parameters. xlab, ...

col Vector of colors for the clusters.

Vector of strings for the strips of the Trellis display. strip.labels strip.prefix

Prefix string for the strips of the Trellis display.

shade If TRUE, only boxes with larger deviation from the median or quartiles of the

total population of the respective variables are filled with color.

shadefun A function or name of a function to compute which boxes are shaded, e.g.

"medianInside" (default) or "boxOverlap".

byvar If TRUE, a panel is plotted for each variable. By default a panel is plotted for

each group.

k Number of clusters.

clusters Integer vector of clusters to plot. cclust 15

# **Examples**

```
set.seed(1)
cl <- cclust(iris[,-5], k=3, save.data=TRUE)
bwplot(cl)
bwplot(cl, byvar=TRUE)

## fill only boxes with color which do not contain the overall median
## (grey dot of background box)
bwplot(cl, shade=TRUE)

## fill only boxes with color which do not overlap with the box of the
## complete sample (grey background box)
bwplot(cl, shadefun="boxOverlap")</pre>
```

cclust

Convex Clustering

# **Description**

Perform k-means clustering, hard competitive learning or neural gas on a data matrix.

## Usage

## **Arguments**

Х	A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
k	Either the number of clusters, or a vector of cluster assignments, or a matrix of initial (distinct) cluster centroids. If a number, a random set of (distinct) rows in $x$ is chosen as the initial centroids.
dist	Distance measure, one of "euclidean" (mean square distance) or "manhattan" (absolute distance).
method	Clustering algorithm: one of "kmeans", "hardcl" or "neuralgas", see details below.
weights	An optional vector of weights for the observations (rows of the x) to be used in the fitting process. Works only in combination with hard competitive learning.
control	An object of class "cclustControl".
group	Currently ignored.
simple	Return an object of class "kccasimple"?
save.data	Save a copy of x in the return object?

16 cclust

#### **Details**

This function uses the same computational engine as the earlier function of the same name from package 'cclust'. The main difference is that it returns an S4 object of class "kcca", hence all available methods for "kcca" objects can be used. By default kcca and cclust use exactly the same algorithm, but cclust will usually be much faster because it uses compiled code.

If dist is "euclidean", the distance between the cluster center and the data points is the Euclidian distance (ordinary kmeans algorithm), and cluster means are used as centroids. If "manhattan", the distance between the cluster center and the data points is the sum of the absolute values of the distances, and the column-wise cluster medians are used as centroids.

If method is "kmeans", the classic kmeans algorithm as given by MacQueen (1967) is used, which works by repeatedly moving all cluster centers to the mean of their respective Voronoi sets. If "hardc1", on-line updates are used (AKA hard competitive learning), which work by randomly drawing an observation from x and moving the closest center towards that point (e.g., Ripley 1996). If "neuralgas" then the neural gas algorithm by Martinetz et al (1993) is used. It is similar to hard competitive learning, but in addition to the closest centroid also the second closest centroid is moved in each iteration.

#### Value

An object of class "kcca".

#### Author(s)

Evgenia Dimitriadou and Friedrich Leisch

#### References

cclustControl-class, kcca
```

clusterSim 17

clusterSim

Cluster Similarity Matrix

## Description

Returns a matrix of cluster similarities. Currently two methods for computing similarities of clusters are implemented, see details below.

# Usage

#### Arguments

object	Fitted object.
data	Data to use for computation of the shadow values. If the cluster object x was created with save.data=TRUE, then these are used by default. Ignored if method="centers".
method	Type of similarities, see details below.
symmetric	Compute symmetric or asymmetric shadow values? Ignored if method="centers".
	Currently not used.

#### Details

If method="shadow" (the default), then the similarity of two clusters is proportional to the number of points in a cluster, where the centroid of the other cluster is second-closest. See Leisch (2006, 2008) for detailed formulas.

If method="centers", then first the pairwise distances between all centroids are computed and rescaled to [0,1]. The similarity between tow clusters is then simply 1 minus the rescaled distance.

```

conversion

Conversion Between S3 Partition Objects and KCCA

# Description

These functions can be used to convert the results from cluster functions like kmeans or pam to objects of class "kcca" and vice versa.

#### Usage

```
## S3 method for class 'hclust'
as.kcca(object, data, k, family=NULL, save.data=FALSE, ...)
## S3 method for class 'kmeans'
as.kcca(object, data, save.data=FALSE, ...)
## S3 method for class 'partition'
as.kcca(object, data=NULL, save.data=FALSE, ...)
## S3 method for class 'skmeans'
as.kcca(object, data, save.data=FALSE, ...)
## S4 method for signature 'kccasimple,kmeans'
coerce(from, to="kmeans", strict=TRUE)
Cutree(tree, k=NULL, h=NULL)
```

conversion 19

## **Arguments**

object Fitted object.

data Data which were used to obtain the clustering. For "partition" objects created by functions from package cluster this is optional, if object contains the data.

save.data Save a copy of the data in the return object?

k Number of clusters.

family Object of class "kccaFamily", can be omitted for some known distances.

... Currently not used.

from, to, strict Usual arguments for coerce

tree A tree as produced by hclust.

h Numeric scalar or vector with heights where the tree should be cut.

#### **Details**

The standard cutree function orders clusters such that observation one is in cluster one, the first observation (as ordered in the data set) not in cluster one is in cluster two, etc. Cutree orders clusters as shown in the dendrogram from left to right such that similar clusters have similar numbers. The latter is used when converting to kcca.

For hierarchical clustering the cluster memberships of the converted object can be different from the result of Cutree, because one KCCA-iteration has to be performed in order to obtain a valid kcca object. In this case a warning is issued.

dist2 21

dist2

Compute Pairwise Distances Between Two Data sets

#### **Description**

This function computes and returns the distance matrix computed by using the specified distance measure to compute the pairwise distances between the rows of two data matrices.

# Usage

```
dist2(x, y, method = "euclidean", p=2)
```

#### **Arguments**

x A data matrix.

y A vector or second data matrix.

method the distance measure to be used. This must be one of "euclidean", "maximum",

"manhattan", "canberra", "binary" or "minkowski". Any unambiguous

substring can be given.

p The power of the Minkowski distance.

#### **Details**

This is a two-data-set equivalent of the standard function dist. It returns a matrix of all pairwise distances between rows in x and y. The current implementation is efficient only if y has not too many rows (the code is vectorized in x but not in y).

#### Note

The definition of Canberra distance was wrong for negative data prior to version 1.3-5.

flexclustControl-class 23

flexclustControl-class

Classes "flexclustControl" and "cclustControl"

#### **Description**

Hyperparameters for cluster algorithms.

#### **Objects from the Class**

Objects can be created by calls of the form new("flexclustControl", ...). In addition, named lists can be coerced to flexclustControl objects, names are completed if unique (see examples).

#### **Slots**

Objects of class "flexclustControl" have the following slots:

iter.max: Maximum number of iterations.

tolerance: The algorithm is stopped when the (relative) change of the optimization criterion is smaller than tolerance.

verbose: If a positive integer, then progress is reported every verbose iterations. If 0, no output is generated during model fitting.

classify: Character string, one of "auto", "weighted", "hard" or "simann".

initcent: Character string, name of function for initial centroids, currently "randomcent" (the default) and "kmeanspp" are available.

gamma: Gamma value for weighted hard competitive learning.

simann: Parameters for simulated annealing optimization (only used when classify="simann").

ntry: Number of trials per iteration for QT clustering.

min. size: Clusters smaller than this value are treated as outliers.

Objects of class "cclustControl" inherit from "flexclustControl" and have the following additional slots:

method: Learning rate for hard competitive learning, one of "polynomial" or "exponential".

pol.rate: Positive number for polynomial learning rate of form  $1/iter^{par}$ .

exp. rate Vector of length 2 with parameters for exponential learning rate of form  $par1*(par2/par1)^{(iter/iter.max)}$ .

ng.rate: Vector of length 4 with parameters for neural gas, see details below.

24 flexclustControl-class

#### **Learning Rate of Neural Gas**

The neural gas algorithm uses updates of form

$$cnew = cold + e * exp(-m/l) * (x - cold)$$

for every centroid, where m is the order (minus 1) of the centroid with respect to distance to data point x (0=closest, 1=second, ...). The parameters e and l are given by

$$e = par1 * (par2/par1)^{(iter/iter.max)},$$
  
 $l = par3 * (par4/par3)^{(iter/iter.max)}.$ 

See Martinetz et al (1993) for details of the algorithm, and the examples section on how to obtain default values.

flxColors 25

flxColors

Flexclust Color Palettes

# Description

Create and access palettes for the plot methods.

#### Usage

```
flxColors(n=1:8, color=c("full","medium", "light","dark"), grey=FALSE)
flxPalette(n, ...)
```

#### **Arguments**

n	Index number of color to return (1 to 8) for flxColor, number of colors to return for flxPalette().
color	Type of color, see details.
grey	Return grey value corresponding to palette.
	Passed on to flxColors().

#### **Details**

This function creates color palettes in HCL space for up to 8 colors. All palettes have constant chroma and luminance, only the hue of the colors change within a palette.

Palettes "full" and "dark" have the same luminance, and palettes "medium" and "light" have the same luminance.

26 histogram-methods

histogram-methods

Methods for Function histogram in Package 'flexclust'

# Description

Plot a histogram of the similarity of each observation to each cluster.

# Usage

## **Arguments**

X	An object of class "kccasimple".
data	If not missing, the distance and thus similarity between observations and cluster centers is determined for the new data and used for the plots. By default the values from the training data are used.
xlab	Label for the x-axis.
power	Numeric indicating how similarities are transformed, for more details see Dolnicar et al. (2018).
	Additional arguments passed to histogram.

## Author(s)

Friedrich Leisch

# References

image-methods 27

image-methods	Methods for Function image in Package 'flexclust'

# Description

Image plot of cluster segments overlaid by neighbourhood graph.

# Usage

# **Arguments**

Х	An object of class "kcca".
which	Index number of dimensions of input space to plot.
npoints	Number of grid points for image.
fastcol	If TRUE, a greedy algorithm is used for the background colors of the segments, which may result in neighbouring segments having the same color. If FALSE, neighbouring segments always have different colors at a speed penalty.
col	Vector of background colors for the segments.
clwd	Line width of contour lines at cluster boundaries, use larger values for npoints than the default to get smooth lines. (Warning: We really need a smarter way to draw cluster boundaries!)
graph	Logical, add a neighborhood graph to the plot?
xlab, ylab,	Graphical parameters.

# **Details**

This works only for "kcca" objects, no method is available for "kccasimple" objects.

28 info

info

Get Information on Fitted Flexclust Objects

#### **Description**

Returns descriptive information about fitted flexclust objects like cluster sizes or sum of withincluster distances.

## Usage

```
## S4 method for signature 'flexclust,character'
info(object, which, drop=TRUE, ...)
```

## Arguments

object Fitted object.

which Which information to get. Use which="help" to list available information.

drop Logical. If TRUE the result is coerced to the lowest possible dimension.

... Passed to methods.

#### **Details**

Function info can be used to access slots of fitted flexclust objects in a portable way, and in addition computes some meta-information like sum of within-cluster distances.

Function infoCheck returns a logical value that is TRUE if the requested information can be computed from the object.

kcca

K-Centroids Cluster Analysis

# **Description**

Perform k-centroids clustering on a data matrix.

## Usage

#### Arguments

x A numeric matrix of data, or an object that can be coerced to such a matrix using data.matrix.

30 kcca

k Either the number of clusters, or a vector of cluster assignments, or a matrix of

initial (distinct) cluster centroids. If a number, a random set of (distinct) rows in

x is chosen as the initial centroids.

family Object of class "kccaFamily".

weights An optional vector of weights to be used in the clustering process, cannot be

combined with all families.

group An optional grouping vector for the data, see details below.

control An object of class "flexclustControl".

simple Return an object of class "kccasimple"?

save.data Save a copy of x in the return object?

which One of "kmeans", "kmedians", "angle", "jaccard", or "ejaccard".

name Optional long name for family, used only for show methods.

A function for distance computation, ignored if which is specified.

A function for centroid computation, ignored if which is specified.

preproc Function for data preprocessing. Defaults to function(x) x.

genDist Function for updating the family object based on x.

trim A number in between 0 and 0.5, if non-zero then trimmed means are used for

the kmeans family, ignored by all other families.

groupFun Function or name of function to obtain clusters for grouped data, see details

below.

object Object of class "kcca".

#### **Details**

See the paper A Toolbox for K-Centroids Cluster Analysis referenced below for details.

#### Value

Function kcca returns objects of class "kcca" or "kccasimple" depending on the value of argument simple. The simpler objects contain fewer slots and hence are faster to compute, but contain no auxiliary information used by the plotting methods. Most plot methods for "kccasimple" objects do nothing and return a warning. If only centroids, cluster membership or prediction for new data are of interest, then the simple objects are sufficient.

#### **Predefined Families**

Function kccaFamily() currently has the following predefined families (distance / centroid):

kmeans: Euclidean distance / meankmedians: Manhattan distance / median

angle: angle between observation and centroid / standardized mean

jaccard: Jaccard distance / numeric optimization

ejaccard: Jaccard distance / mean

See Leisch (2006) for details on all combinations.

kcca 31

#### **Group Constraints**

If group is not NULL, then observations from the same group are restricted to belong to the same cluster (must-link constraint) or different clusters (cannot-link constraint) during the fitting process. If groupFun = "minSumClusters", then all group members are assign to the cluster where the center has minimal average distance to the group members. If groupFun = "majorityClusters", then all group members are assigned to the cluster the majority would belong to without a constraint.

groupFun = "differentClusters" implements a cannot-link constraint, i.e., members of one group are not allowed to belong to the same cluster. The optimal allocation for each group is found by solving a linear sum assignment problem using solve\_LSAP. Obviously the group sizes must be smaller than the number of clusters in this case.

Ties are broken at random in all cases. Note that at the moment not all methods for fitted "kcca" objects respect the grouping information, most importantly the plot method when a data argument is specified.

plot-methods

Methods for Function plot in Package 'flexclust'

# Description

Plot the neighbourhood graph of a cluster solution together with projected data points.

# Usage

36 plot-methods

#### **Arguments**

x An object of class "kcca"

y Not used

which Index numbers of dimensions of (projected) input space to plot.

project Projection object for which a predict method exists, e.g., the result of prcomp.

data Data to include in plot. If the cluster object x was created with save.data=TRUE,

then these are used by default.

points Logical, shall data points be plotted (if available)?

hull If TRUE, then hulls of the data are plotted (if available). Can either be a logical

value, one of the strings "convex" (the default) or "ellipse", or a function for

plotting the hulls.

hull.args A list of arguments for the hull function.

number Logical, plot number labels in nodes of graph?

numcol, cex Color and size of number labels in nodes of graph. If numcol is logical, it

switches between black and the color of the clusters, else it is taken as a vector

of colors.

nodes Plotting symbol to use for nodes if no numbers are drawn.

simlines Logical, plot edges of graph?

lwd, maxlwd Numerical, thickness of lines.

add Logical, add to existing plot?

xlab, ylab Axis labels. xlim, ylim Axis range.

pch, col, ... Plotting symbols and colors for data points.

# Details

This works only for "kcca" objects, no method is available for "kccasimple" objects.

predict-methods 37

predict-methods	Predict Cluster Membership
-----------------	----------------------------

## **Description**

Return either the cluster membership of training data or predict for new data.

## Usage

```
## S4 method for signature 'kccasimple'
predict(object, newdata, ...)
## S4 method for signature 'flexclust,ANY'
clusters(object, newdata, ...)
```

## **Arguments**

object Object of class inheriting from "flexclust".

newdata An optional data matrix with the same number of columns as the cluster centers.

If omitted, the fitted values are used.

... Currently not used.

## **Details**

clusters can be used on any object of class "flexclust" and returns the cluster memberships of the training data.

predict can be used only on objects of class "kcca" (which inherit from "flexclust"). If no newdata argument is specified, the function is identical to clusters, if newdata is specified, then cluster memberships for the new data are predicted. clusters(object, newdata, ...) is an alias for predict(object, newdata, ...).

projAxes

Add Arrows for Projected Axes to a Plot

# Description

Adds arrows for original coordinate axes to a projection plot.

# Usage

projAxes 39

## **Arguments**

object Return value of a projection method like prcomp. which Index number of dimensions of (projected) input space that have been plotted. Center of the coordinate system to use in projected space. Default is the center center of the plotting region. Color of arrows. col radius Relative size of the arrows. minradius Minimum radius of arrows to include (relative to arrow size). textargs List of arguments for text. Variable names of the original data. col.names which.names A regular expression which variable names to include in the plot. An optional grouping variable for the original coordinates. Coordinates with group group NA are omitted. groupFun Function used to aggregate the projected coordinates if group is specified. plot Logical, if TRUE the axes are added to the current plot.

... Passed to arrows.

## Value

projAxes invisibly returns an object of class "projAxes", which can be added to an existing plot by its plot method.

#### Author(s)

Friedrich Leisch

```

propBarchart

Barcharts and Boxplots for Columns of a Data Matrix Split by Groups

# **Description**

Split a binary or numeric matrix by a grouping variable, run a series of tests on all variables, adjust for multiple testing and graphically represent results.

# Usage

# Arguments

**	11 oniary and marrie
g	A factor specifying the groups.
alpha	Significance level for test of differences in proportions.
correct	Correction method for multiple testing, passed to p.adjust.
test	Test to use for detecting significant differences in proportions.

A binary data matrix.

propBarchart 41

sort	Logical, sort variables by total sample mean?
strip.prefix	Character string prepended to strips of the barchart (the remainder of the strip are group levels and group sizes). Ignored if strip.labels is specified.
strip.labels	Character vector of labels to use for strips of barchart.
which	Index numbers or names of variables to plot.
byvar	If TRUE, a panel is plotted for each variable. By default a panel is plotted for each group.
• • •	Passed on to barchart or bwplot.
object	Return value of propBarchart.
xlab	A title for the x-axis: see title. The default is "".
col	Vector of colors for the panels.
shade	If TRUE, only variables with significant differences in median are filled with color.
shadefun	A function or name of a function to compute which boxes are shaded, e.g. "kruskalTest" (default), "medianInside" or "boxOverlap".

## **Details**

Function propBarchart splits a binary data matrix into subgroups, computes the percentage of ones in each column and compares the proportions in the groups using prop.test. The p-values for all variables are adjusted for multiple testing and a barchart of group percentages is drawn highlighting variables with significant differences in proportion. The summary method can be used to create a corresponding table for publications.

Function groupBWplot takes a general numeric matrix, also splits into subgroups and uses boxes instead of bars. By default kruskal.test is used to compute significant differences in location, in addition the heuristics from bwplot,kcca-method can be used. Boxes of the complete sample are used as reference in the background.

qtclust

Stochastic QT Clustering

## **Description**

Perform stochastic QT clustering on a data matrix.

## Usage

## **Arguments**

х	A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
radius	Maximum radius of clusters.
family	Object of class "kccaFamily" specifying the distance measure to be used.
control	An object of class "flexclustControl" specifying the minimum number of observations per cluster (min.size), and trials per iteration (ntry, see details below).
•	
save.data	Save a copy of x in the return object?
kcca	Run kcca after the QT cluster algorithm has converged?

## **Details**

This function implements a variation of the QT clustering algorithm by Heyer et al. (1999), see Scharl and Leisch (2006). The main difference is that in each iteration not all possible cluster start points are considered, but only a random sample of size control@ntry. We also consider only points as initial centers where at least one other point is within a circle with radius radius. In most cases the resulting solutions are almost the same at a considerable speed increase, in some cases even better solutions are obtained than with the original algorithm. If control@ntry is set to the size of the data set, an algorithm similar to the original algorithm as proposed by Heyer et al. (1999) is obtained.

randIndex 43

## Value

Function qtclust by default returns objects of class "kccasimple". If argument kcca is TRUE, function kcca() is run afterwards (initialized on the QT cluster solution). Data points not clustered by the QT cluster algorithm are omitted from the kcca() iterations, but filled back into the return object. All plot methods defined for objects of class "kcca" can be used.

## **Examples**

```
x <- matrix(10*runif(1000), ncol=2)

## maximum distrance of point to cluster center is 3
cl1 <- qtclust(x, radius=3)

## maximum distrance of point to cluster center is 1

## -> more clusters, longer runtime
cl2 <- qtclust(x, radius=1)

opar <- par(c("mfrow","mar"))
par(mfrow=c(2,1), mar=c(2.1,2.1,1,1))
plot(x, col=predict(cl1), xlab="", ylab="")
plot(x, col=predict(cl2), xlab="", ylab="")
par(opar)</pre>
```

randIndex

Compare Partitions

## **Description**

Compute the (adjusted) Rand, Jaccard and Fowlkes-Mallows index for agreement of two partitions.

44 randIndex

#### Usage

```
comPart(x, y, type=c("ARI","RI","J","FM"))
## S4 method for signature 'flexclust,flexclust'
comPart(x, y, type)
## S4 method for signature 'numeric,numeric'
comPart(x, y, type)
## S4 method for signature 'flexclust,numeric'
comPart(x, y, type)
## S4 method for signature 'numeric,flexclust'
comPart(x, y, type)

randIndex(x, y, correct=TRUE, original=!correct)
## S4 method for signature 'table,missing'
randIndex(x, y, correct=TRUE, original=!correct)
## S4 method for signature 'ANY,ANY'
randIndex(x, y, correct=TRUE, original=!correct)
```

## **Arguments**

x Either a 2-dimensional cross-tabulation of cluster assignments (for randIndex only), an object inheriting from class "flexclust", or an integer vector of cluster memberships.

y An object inheriting from class "flexclust", or an integer vector of cluster memberships.

type character vector of abbreviations of indices to compute.

correct, original

Logical, correct the Rand index for agreement by chance?

#### Value

A vector of indices.

#### **Rand Index**

Let A denote the number of all pairs of data points which are either put into the same cluster by both partitions or put into different clusters by both partitions. Conversely, let D denote the number of all pairs of data points that are put into one cluster in one partition, but into different clusters by the other partition. The partitions disagree for all pairs D and agree for all pairs A. We can measure the agreement by the Rand index A/(A+D) which is invariant with respect to permutations of cluster labels.

The index has to be corrected for agreement by chance if the sizes of the clusters are not uniform (which is usually the case), or if there are many clusters, see Hubert & Arabie (1985) for details.

#### **Jaccard Index**

If the number of clusters is very large, then usually the vast majority of pairs of points will not be in the same cluster. The Jaccard index tries to account for this by using only pairs of points that are in the same cluster in the defintion of A.

randomTour 45

## Fowlkes-Mallows

Let A again be the pairs of points that are in the same cluster in both partitions. Fowlkes-Mallows divides this number by the geometric mean of the sums of the number of pairs in each cluster of the two partitions. This gives the probability that a pair of points which are in the same cluster in one partition are also in the same cluster in the other partition.

Marina Meila. Comparing clusterings - an axiomatic view. In Stefan Wrobel and Luc De Raedt, editors, Proceedings of the International Machine Learning Conference (ICML). ACM Press, 2005.

## **Examples**

```
## no class correlations: corrected Rand almost zero
g1 <- sample(1:5, size=1000, replace=TRUE)</pre>
g2 <- sample(1:5, size=1000, replace=TRUE)
tab <- table(g1, g2)
randIndex(tab)
## uncorrected version will be large, because there are many points
## which are assigned to different clusters in both cases
randIndex(tab, correct=FALSE)
comPart(g1, g2)
## let pairs (g1=1,g2=1) and (g1=3,g2=3) agree better
k <- sample(1:1000, size=200)
g1[k] <- 1
g2[k] <- 1
k <- sample(1:1000, size=200)
g1[k] < -3
g2[k] < -3
tab <- table(g1, g2)
## the index should be larger than before
randIndex(tab, correct=TRUE, original=TRUE)
comPart(g1, g2)
```

randomTour

Plot a Random Tour

## **Description**

Create a series of projection plots corresponding to a random tour through the data.

46 randomTour

#### Usage

## **Arguments**

object, x	A matrix or an	object of class	"flexclust".

data Data to include in plot.

col Plotting colors for data points.

directions Integer value, how many different directions are toured.

steps Integer, number of steps in each direction.

sec Numerical, lower bound for the number of seconds each direction takes.

Sleep Numerical, sleep for as many seconds after each picture has been plotted.

axiscol If not NULL, then arrows are plotted for projections of the original coordinate

axes in these colors.

axislab Optional labels for the projected axes.

center Center of the coordinate system to use in projected space. Default is the center

of the plotting region.

radius Relative size of the arrows.

minradius Minimum radius of arrows to include.

asp, ... Passed on to randomTourMatrix and from there to plot.

#### **Details**

Two random locations are chosen, and data then projected onto hyperplanes which are orthogonal to step vectors interpolating the two locations. The first two coordinates of the projected data are plotted. If directions is larger than one, then after the first steps plots one more random location is chosen, and the procedure is repeated from the current position to the new location, etc..

The whole procedure is similar to a grand tour, but no attempt is made to optimize subsequent directions, randomTour simply chooses a random direction in each iteration. Use rggobi for the real thing.

Obviously the function needs a reasonably fast computer and graphics device to give a smooth impression, for x11 it may be necessary to use type="Xlib" rather than cairo.

relabel 47

#### Author(s)

Friedrich Leisch

#### **Examples**

relabel

Relabel Cluster Results.

#### Description

The clusters are relabelled to obtain a unique labeling.

#### Usage

```
relabel(object, by, ...)
## S4 method for signature 'kccasimple,character'
relabel(object, by, which = NULL, ...)
## S4 method for signature 'kccasimple,integer'
relabel(object, by, ...)
## S4 method for signature 'kccasimple,missing'
relabel(object, by, ...)
## S4 method for signature 'stepFlexclust,integer'
relabel(object, by = "series", ...)
## S4 method for signature 'stepFlexclust,missing'
relabel(object, by, ...)
```

# **Arguments**

object An object of class "kccasimple" or "stepFlexclust".

by If a character vector, it needs to be one of "mean", "median", "variable",
 "manual", "centers", "shadow", "symmshadow" or "series". If missing,
 "mean" or "series" is used depending on if object is of class "kccasimple"
 or "stepFlexclust". If an integer vector, it needs to indicate the new ordering.

48 shadow

which Either an integer vector indiating the ordering or a vector of length one indicating the variable used for ordering.

... Currently not used.

#### **Details**

If by is a character vector with value "mean" or "median", the clusters are ordered by the mean or median values over all variables for each cluster. If by = "manual" which needs to be a vector indicating the ordering. If by = "variable" which needs to be indicate the variable which is used to determine the ordering. If by is "centers", "shadow" or "symmshadow", cluster similarities are calculated using clusterSim and used to determine an ordering using seriate from package seriation.

If by = "series" the relabeling is performed over a series of clustering to minimize the misclassification.

shadow

Cluster Shadows and Silhouettes

# Description

Compute and plot shadows and silhouettes.

## Usage

```
## $4 method for signature 'kccasimple'
shadow(object, ...)
## $4 method for signature 'kcca'
Silhouette(object, data=NULL, ...)
```

# **Arguments**

object An object of class "kcca" or "kccasimple".

data Data to compute silhouette values for. If the cluster object was created with

save.data=TRUE, then these are used by default.

... Currently not used.

shadow 49

#### **Details**

The shadow value of each data point is defined as twice the distance to the closest centroid divided by the sum of distances to closest and second-closest centroid. If the shadow values of a point is close to 0, then the point is close to its cluster centroid. If the shadow value is close to 1, it is almost equidistant to the two centroids. Thus, a cluster that is well separated from all other clusters should have many points with small shadow values.

The silhouette value of a data point is defined as the scaled difference between the average dissimilarity of a point to all points in its own cluster to the smallest average dissimilarity to the points of a different cluster. Large silhouette values indicate good separation.

The main difference between silhouette values and shadow values is that we replace average dissimilarities to points in a cluster by dissimilarities to point averages (=centroids). See Leisch (2009) for details.

```

50 shadowStars

|--|

## **Description**

Shadow star plots and corresponding panel functions.

# Usage

## **Arguments**

object	An object of class "kcca".
object	All object of class RCCa.
which	Index numbers of dimensions of (projected) input space to plot.
project	Projection object for which a predict method exists, e.g., the result of prcomp.
width	Width of vertices connecting the cluster centroids.
varwidth	Logical, shall all vertices have the same width or should the width be proportional to number of points shown on the vertex?
panel	Function used to draw vertices.
box	Color of rectangle drawn around each vertex.
col	A vector of colors for the clusters.
add	Logical, start a new plot?
	Passed on to panel function.
x	Shadow values of data points corresponding to the vertex.

## **Details**

The shadow value of each data point is defined as twice the distance to the closest centroid divided by the sum of distances to closest and second-closest centroid. If the shadow values of a point is close to 0, then the point is close to its cluster centroid. If the shadow value is close to 1, it is almost equidistant to the two centroids. Thus, a cluster that is well separated from all other clusters should have many points with small shadow values.

The neighborhood graph of a cluster solution connects two centroids by a vertex if at least one data point has the two centroids as closest and second closest. The width of the vertex is proportional to

shadowStars 51

the sum of shadow values of all points having these two as closest and second closest. A shadow star depicts the distribution of shadow values on the vertex, see Leisch (2009) for details.

Currently four panel functions are available:

```
panelShadowStripes: line segment for each shadow value.

panelShadowViolin: violin plot of shadow values.

panelShadowBP: box-percentile plot of shadow values.

panelShadowSkeleton: average shadow value.
```

52 slsaplot

slsaplot

Segment Level Stability Across Solutions Plot.

# Description

Create a segment level stability across solutions plot, possibly using an additional variable for coloring the nodes.

# Usage

```
slsaplot(object, nodecol = NULL, ...)
```

# Arguments

object An object returned by stepFlexclust.

nodecol A numeric vector of length equal to the number of observations clustered in

object which represents an additional variable where a cluster-specific mean is

calculated and used to color the nodes.

... Additional graphical parameters to modify the plot.

# **Details**

For more details see Dolnicar and Leisch (2017) and Dolnicar et al. (2018).

## Value

List of length equal to the number of different cluster solutions minus one containing numeric vectors of the entropy values used by default to color the nodes.

# Author(s)

Friedrich Leisch

## References

slsaplot(cl25)
cl25 <- relabel(cl25)
slsaplot(cl25)</pre>
```

slswFlexclust

Segment Level Stability Within Solution.

## **Description**

Assess segment level stability within solution.

# Usage

```
slswFlexclust(x, object, ...)
## S4 method for signature 'resampleFlexclust,missing'
plot(x, y, ...)
## S4 method for signature 'resampleFlexclust'
boxplot(x, which=1, ylab=NULL, ...)
## S4 method for signature 'resampleFlexclust'
densityplot(x, data, which=1, ...)
## S4 method for signature 'resampleFlexclust'
summary(object)
```

## **Arguments**

Х	A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns) passed to stepFlexclust.
object	Object of class "kcca" for slwsFlexclust and "resampleFlexclust" for the summary method.
у	Missing.
which	Integer or character indicating which validation measure is used for plotting.
ylab	Axis label.
data	Not used.
	Additional arguments; for details see below.

## **Details**

Additional arguments in slswFlexclust are argument nsamp which is by default equal to 100 and allows to change the number of bootstrap pairs drawn. Argument seed allows to set a random seed and argument multicore is by default TRUE and indicates if bootstrap samples should be drawn in parallel. Argument verbose is by default equal to FALSE and if TRUE progress information is shown during computations.

54 stepFlexclust

There are plotting as well as printing and summary methods implemented for objects of class "resampleFlexclust". In addition to a standard plot method also methods for densityplot and boxplot are provided.

For more details see Dolnicar and Leisch (2017) and Dolnicar et al. (2018).

## Value

An object of class "resampleFlexclust".

stepFlexclust

Run Flexclust Algorithms Repeatedly

# Description

Runs clustering algorithms repeatedly for different numbers of clusters and returns the minimum within cluster distance solution for each.

stepFlexclust 55

# Usage

# **Arguments**

x,	Passed to kcca or cclust.
k	A vector of integers passed in turn to the k argument of kcca
nrep	For each value of k run kcca nrep times and keep only the best solution.
FUN	Cluster function to use, typically kcca or cclust.
verbose	If TRUE, show progress information during computations.
drop	If TRUE and K is of length 1, then a single cluster object is returned instead of a "stepFlexclust" object.
group	An optional grouping vector for the data, see kcca for details.
simple	Return an object of class "kccasimple"?
save.data	Save a copy of x in the return object?
seed	If not NULL, a call to set.seed() is made before any clustering is done.
multicore	If TRUE, use mclapply() from package <b>parallel</b> for parallel processing.
У	Not used.
type	Create a barplot or lines plot.
totaldist	Include value for 1-cluster solution in plot? Default is TRUE if K contains 2, else FALSE.
xlab, ylab	Graphical parameters.
object	Object of class "stepFlexclust".
which	Number of model to get. If character, interpreted as number of clusters.

#### **Details**

```
stepcclust is a simple wrapper for stepFlexclust(...,FUN=cclust).
```

# Author(s)

Friedrich Leisch

56 stripes

## **Examples**

```
data("Nclus")
plot(Nclus)
## multicore off for CRAN checks
cl1 <- stepFlexclust(Nclus, k=2:7, FUN=cclust, multicore=FALSE)</pre>
cl1
plot(cl1)
# two ways to do the same:
getModel(cl1, 4)
cl1[[4]]
opar <- par("mfrow")</pre>
par(mfrow=c(2, 2))
for(k in 3:6){
  image(getModel(cl1, as.character(k)), data=Nclus)
  title(main=paste(k, "clusters"))
}
par(opar)
```

stripes

Stripes Plot

## **Description**

Plot distance of data points to cluster centroids using stripes.

## Usage

```
stripes(object, groups=NULL, type=c("first", "second", "all"),
    beside=(type!="first"), col=NULL, gp.line=NULL, gp.bar=NULL,
    gp.bar2=NULL, number=TRUE, legend=!is.null(groups),
    ylim=NULL, ylab="distance from centroid",
    margins=c(2,5,3,2), ...)
```

## **Arguments**

object An object of class "kcca".

groups Grouping variable to color-code the stripes. By default cluster membership is

used as groups.

type Plot distance to closest, closest and second-closest or to all centroids?

beside Logical, make different stripes for different clusters?

col Vector of colors for clusters or groups.

gp.line, gp.bar, gp.bar2

Graphical parameters for horizontal lines and background rectangular areas, see

gpar.

stripes 57

number Logical, write cluster numbers on x-axis?

legend Logical, plot a legend for the groups?

ylim, ylab Graphical parameters for y-axis.

margins Margin of the plot.

... Further graphical parameters.

#### **Details**

A simple, yet very effective plot for visualizing the distance of each point from its closest and second-closest cluster centroids is a stripes plot. For each of the k clusters we have a rectangular area, which we optionally vertically divide into k smaller rectangles (beside=TRUE). Then we draw a horizontal line segment for each data point marking the distance of the data point from the corresponding centroid.

58 vacmot

vacmot

Vacation Motives of Australians

#### **Description**

In 2006 a sample of 1000 respondents representative for the adult Australian population was asked about their environmental behaviour when on vacation. In addition the survey also included a list of statements about vacation motives like "I want to rest and relax," "I use my holiday for the health and beauty of my body," and "Cultural offers and sights are a crucial factor.". Answers are binary ("applies", "does not apply").

# Usage

```
data(vacmot)
```

#### **Format**

Data frame vacmot has 1000 observations on 20 binary variables on travel motives. Data frame vacmotdesc has 1000 observation on sociodemographic descriptor variables, mean moral obligation to protect the environment score, mean NEP score, and mean environmental behaviour score, see Dolnicar & Leisch (2008) for details. In addition integer vector vacmot6 contains the 6 cluster partition presented in Dolnicar & Leisch (2008).

## Source

The data set was collected by the Institute for Innovation in Business and Social Research, University of Wollongong (NSW, Australia).

Motivation of Australian Volunteers

# **Description**

Part of an Australian survey on motivation of volunteers to work for non-profit organisations like Red Cross, State Emergency Service, Rural Fire Service, Surf Life Saving, Rotary, Parents and Citizens Associations, etc..

## Usage

data(volunteers)

#### **Format**

A data frame with 1415 observations on the following 21 variables: age and gender of respondents plus 19 binary motivation items (1 applies/ 0 does not apply).

GENDER Gender of respondent.

AGEG Age group, a factor with categorized age of respondents.

meet.people I can meet different types of people.

no.one.else There is no-one else to do the work.

example It sets a good example for others.

socialise I can socialise with people who are like me.

help.others It gives me the chance to help others.

give.back I can give something back to society.

career It will help my career prospects.

lonely It makes me feel less lonely.

active It keeps me active.

community It will improve my community.

cause I can support an important cause.

faith I can put faith into action.

services I want to maintain services that I may use one day.

children My children are involved with the organisation.

good. job I feel like I am doing a good job.

benefited I know someone who has benefited from the organisation.

network I can build a network of contacts.

recognition I can gain recognition within the community.

mind.off It takes my mind off other things.

60 volunteers

## **Source**

The volunteering data was collected by the Institute for Innovation in Business and Social Research, University of Wollongong (NSW, Australia), using funding from Bushcare Wollongong and the Australian Research Council under the ARC Linkage Grant scheme (LP0453682).
