Package 'ggstats'

September 22, 2024

Type Package

Title Extension to 'ggplot2' for Plotting Stats

Version 0.7.0

Description Provides new statistics, new geometries and new positions for 'ggplot2' and a suite of functions to facilitate the creation of statistical plots.

License GPL (>= 3)

URL https://larmarange.github.io/ggstats/, https://github.com/larmarange/ggstats

BugReports https://github.com/larmarange/ggstats/issues

Depends R (>= 4.2)

Imports cli, dplyr, forcats, ggplot2 (>= 3.4.0), lifecycle, patchwork, purrr, rlang, scales, stats, stringr, tidyr

Suggests betareg, broom, broom.helpers (>= 1.17.0), emmeans, glue, gtsummary, knitr, labelled (>= 2.11.0), reshape, rmarkdown, nnet, parameters, pscl, testthat (>= 3.0.0), spelling, survey, survival, vdiffr

Encoding UTF-8

RoxygenNote 7.3.2

Config/testthat/edition 3

Language en-US

VignetteBuilder knitr

NeedsCompilation no

`augment_chisq_add_phi` *Augment a chi-squared test and compute phi coefficients*

Description

Augment a chi-squared test and compute phi coefficients

Usage

```
augment_chisq_add_phi(x)
```

Arguments

`x`	a chi-squared test as returned by `stats::chisq.test()`

Details

Phi coefficients are a measurement of the degree of association between two binary variables.

- A value between -1.0 to -0.7 indicates a strong negative association.
- A value between -0.7 to -0.3 indicates a weak negative association.
- A value between -0.3 to +0.3 indicates a little or no association.
- A value between +0.3 to +0.7 indicates a weak positive association.
- A value between +0.7 to +1.0 indicates a strong positive association.

Value

A tibble.

See Also

stat_cross(), GDAtools::phi.table() or psych::phi()

Examples

```
tab <- xtabs(Freq ~ Sex + Class, data = as.data.frame(Titanic))
augment_chisq_add_phi(chisq.test(tab))
```

---

geom_diverging *Geometries for diverging bar plots*

Description

These geometries are similar to ggplot2::geom_bar() but provides different set of default values.

Usage

```
geom_diverging(
  mapping = NULL,
  data = NULL,
  stat = "prop",
  position = position_diverging(reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = "fill",
  default_by = "total",
  height = "count",
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL
)

geom_likert(
  mapping = NULL,
  data = NULL,
  stat = "prop",
  position = position_likert(reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = "fill",
  default_by = "x",
  height = "prop",
  reverse = FALSE,
```

```
  exclude_fill_values = NULL,
  cutoff = NULL
)

geom_pyramid(
  mapping = NULL,
  data = NULL,
  stat = "prop",
  position = position_diverging(reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = NULL,
  default_by = "total",
  height = "prop",
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL
)

geom_diverging_text(
  mapping = NULL,
  data = NULL,
  stat = "prop",
 position = position_diverging(vjust = vjust, reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = "fill",
  default_by = "total",
  height = "count",
  labels = "count",
  labeller = label_number_abs(hide_below = hide_below),
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL,
  vjust = 0.5,
  hide_below = NULL
)

geom_likert_text(
  mapping = NULL,
  data = NULL,
  stat = "prop",
 position = position_likert(vjust = vjust, reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = "fill",
  default_by = "x",
  height = "prop",
```

```
  labels = "prop",
  labeller = label_percent_abs(accuracy = 1, hide_below = hide_below),
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL,
  vjust = 0.5,
  hide_below = NULL
)

geom_pyramid_text(
  mapping = NULL,
  data = NULL,
  stat = "prop",
 position = position_diverging(vjust = vjust, reverse = reverse, exclude_fill_values =
    exclude_fill_values, cutoff = cutoff),
  ...,
  complete = NULL,
  default_by = "total",
  height = "prop",
  labels = "prop",
  labeller = label_percent_abs(accuracy = 1, hide_below = hide_below),
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL,
  vjust = 0.5,
  hide_below = NULL
)
```

Arguments

mapping	Optional set of aesthetic mappings.
data	The data to be displayed in this layers.
stat	The statistical transformation to use on the data for this layer.
position	A position adjustment to use on the data for this layer.
...	Other arguments passed on to ggplot2::geom_bar()
complete	An aesthetic for those unobserved values should be completed, see stat_prop(). Passed only if stat = "prop".
default_by	Name of an aesthetic determining denominators by default, see stat_prop(). Passed only if stat = "prop".
height	Statistic used, by default, to determine the height/width, see stat_prop(). Passed only if stat = "prop".
reverse	If TRUE, will reverse the default stacking order. This is useful if you're rotating both the plot and legend.
exclude_fill_values	Vector of values from the variable associated with the fill aesthetic that should not be displayed (but still taken into account for computing proportions)

cutoff	number of categories to be displayed negatively (i.e. on the left of the x axis or the bottom of the y axis), could be a decimal value: `2` to display negatively the two first categories, `2.5` to display negatively the two first categories and half of the third, `2.2` to display negatively the two first categories and a fifth of the third (see examples). By default (`NULL`), it will be equal to the number of categories divided by 2, i.e. it will be centered.
labels	Statistic used, by default, to determine the labels, see `stat_prop()`. Passed only if `stat = "prop"`.
labeller	Labeller function to format labels, see `stat_prop()`. Passed only if `stat = "prop"`.
vjust	Vertical adjustment for geoms that have a position (like points or lines), not a dimension (like bars or areas). Set to `0` to align with the bottom, `0.5` for the middle, and `1` (the default) for the top.
hide_below	If provided, values below `hide_below` will be masked. Argument passed to `label_number_abs()` or `label_percent_abs()`.

Details

- `geom_diverging()` is designed for stacked diverging bar plots, using `position_diverging()`.
- `geom_likert()` is designed for Likert-type items. Using `position_likert()` (each bar sums to 100%).
- `geom_pyramid()` is similar to `geom_diverging()` but uses proportions of the total instead of counts.

To add labels on the bar plots, simply use `geom_diverging_text()`, `geom_likert_text()`, or `geom_pyramid_text()`.

Examples

```
library(ggplot2)
ggplot(diamonds) +
  aes(x = clarity, fill = cut) +
  geom_diverging()

ggplot(diamonds) +
  aes(x = clarity, fill = cut) +
  geom_diverging(cutoff = 4)

ggplot(diamonds) +
  aes(y = clarity, fill = cut) +
  geom_likert() +
  geom_likert_text(aes(color = after_scale(hex_bw(.data$fill))))

d <- Titanic |> as.data.frame()

ggplot(d) +
  aes(y = Class, fill = Sex, weight = Freq) +
  geom_diverging() +
  geom_diverging_text()
```

```
ggplot(d) +
  aes(y = Class, fill = Sex, weight = Freq) +
  geom_pyramid() +
  geom_pyramid_text()
```

`geom_stripped_rows` *Alternating Background Color*

Description

Add alternating background color along the y-axis. The geom takes default aesthetics `odd` and `even` that receive color codes.

Usage

```
geom_stripped_rows(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...,
  show.legend = NA,
  inherit.aes = TRUE,
  xfrom = -Inf,
  xto = Inf,
  width = 1,
  nudge_y = 0
)

geom_stripped_cols(
  mapping = NULL,
  data = NULL,
  stat = "identity",
  position = "identity",
  ...,
  show.legend = NA,
  inherit.aes = TRUE,
  yfrom = -Inf,
  yto = Inf,
  width = 1,
  nudge_x = 0
)
```

Arguments

`mapping`	Set of aesthetic mappings created by `aes()`. If specified and `inherit.aes = TRUE` (the default), it is combined with the default mapping at the top level of the plot. You must supply `mapping` if there is no plot mapping.

`data` The data to be displayed in this layer. There are three options:

If `NULL`, the default, the data is inherited from the plot data as specified in the call to `ggplot()`.

A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See `fortify()` for which variables will be created.

A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A `function` can be created from a `formula` (e.g. `~ head(.x, 10)`).

`stat` The statistical transformation to use on the data for this layer. When using a `geom_*()` function to construct a layer, the `stat` argument can be used the override the default coupling between geoms and stats. The `stat` argument accepts the following:

- A `Stat` ggproto subclass, for example `StatCount`.
- A string naming the stat. To give the stat as a string, strip the function name of the `stat_` prefix. For example, to use `stat_count()`, give the stat as `"count"`.
- For more information and other ways to specify the stat, see the layer stat documentation.

`position` A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The `position` argument accepts the following:

- The result of calling a position function, such as `position_jitter()`. This method allows for passing extra arguments to the position.
- A string naming the position adjustment. To give the position as a string, strip the function name of the `position_` prefix. For example, to use `position_jitter()`, give the position as `"jitter"`.
- For more information and other ways to specify the position, see the layer position documentation.

`...` Other arguments passed on to `layer()`'s `params` argument. These arguments broadly fall into one of 4 categories below. Notably, further arguments to the `position` argument, or aesthetics that are required can *not* be passed through `....` Unknown arguments that are not part of the 4 categories below are ignored.

- Static aesthetics that are not mapped to a scale, but are at a fixed value and apply to the layer as a whole. For example, `colour = "red"` or `linewidth = 3`. The geom's documentation has an **Aesthetics** section that lists the available options. The 'required' aesthetics cannot be passed on to the `params`. Please note that while passing unmapped aesthetics as vectors is technically possible, the order and required length is not guaranteed to be parallel to the input data.
- When constructing a layer using a `stat_*()` function, the `...` argument can be used to pass on parameters to the `geom` part of the layer. An example of this is `stat_density(geom = "area", outline.type = "both")`. The geom's documentation lists which parameters it can accept.
- Inversely, when constructing a layer using a `geom_*()` function, the `...` argument can be used to pass on parameters to the `stat` part of the layer.

An example of this is `geom_area(stat = "density", adjust = 0.5)`. The stat's documentation lists which parameters it can accept.

- The `key_glyph` argument of `layer()` may also be passed on through `...`. This can be one of the functions described as key glyphs, to change the display of the layer in the legend.

`show.legend` logical. Should this layer be included in the legends? `NA`, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes. It can also be a named logical vector to finely select the aesthetics to display.

`inherit.aes` If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. `borders()`.

`xfrom, xto` limitation of the strips along the x-axis

`width` width of the strips

`yfrom, yto` limitation of the strips along the y-axis

`nudge_x, nudge_y` horizontal or vertical adjustment to nudge strips by

Value

A `ggplot2` plot with the added geometry.

Examples

```
data(tips, package = "reshape")

library(ggplot2)
p <- ggplot(tips) +
  aes(x = time, y = day) +
  geom_count() +
  theme_light()

p
p + geom_stripped_rows()
p + geom_stripped_cols()
p + geom_stripped_rows() + geom_stripped_cols()

p <- ggplot(tips) +
  aes(x = total_bill, y = day) +
  geom_count() +
  theme_light()
p
p + geom_stripped_rows()
p + geom_stripped_rows() + scale_y_discrete(expand = expansion(0, 0.5))
p + geom_stripped_rows(xfrom = 10, xto = 35)
p + geom_stripped_rows(odd = "blue", even = "yellow")
p + geom_stripped_rows(odd = "blue", even = "yellow", alpha = .1)
p + geom_stripped_rows(odd = "#00FF0022", even = "#FF000022")
```

```
p + geom_stripped_cols()
p + geom_stripped_cols(width = 10)
p + geom_stripped_cols(width = 10, nudge_x = 5)
```

---

ggcascade *Cascade plot*

Description

[Experimental]

Usage

```
ggcascade(
  .data,
  ...,
  .weights = NULL,
  .by = NULL,
  .nrow = NULL,
  .ncol = NULL,
  .add_n = TRUE,
  .text_size = 4,
  .arrows = TRUE
)

compute_cascade(.data, ..., .weights = NULL, .by = NULL)

plot_cascade(
  .data,
  .by = NULL,
  .nrow = NULL,
  .ncol = NULL,
  .add_n = TRUE,
  .text_size = 4,
  .arrows = TRUE
)
```

Arguments

`.data`	A data frame, or data frame extension (e.g. a tibble). For `plot_cascade()`, the variable displayed on the x-axis should be named `"x"` and the number of observations should be named `"n"`, like the tibble returned by `compute_cascade()`.
`...`	<data-masking> Name-value pairs of conditions defining the different statuses to be plotted (see examples).
`.weights`	<tidy-select> Optional weights. Should select only one variable.

.by	<tidy-select> A variable or a set of variables to group by the computation of the cascade, and to generate facets. To select several variables, use dplyr::pick() (see examples).
.nrow, .ncol	Number of rows and columns, for faceted plots.
.add_n	Display the number of observations?
.text_size	Size of the labels, passed to ggplot2::geom_text().
.arrows	Display arrows between statuses?

Details

ggcascade() calls compute_cascade() to generate a data set passed to plot_cascade(). Use compute_cascade() and plot_cascade() for more controls.

Value

A ggplot2 plot or a tibble.

Examples

```
ggplot2::diamonds |>
  ggcascade(
    all = TRUE,
    big = carat > .5,
    "big & ideal" = carat > .5 & cut == "Ideal"
  )

ggplot2::mpg |>
  ggcascade(
    all = TRUE,
    recent = year > 2000,
    "recent & economic" = year > 2000 & displ < 3,
    .by = cyl,
    .ncol = 3,
    .arrows = FALSE,
    .text_size = 3
  )

ggplot2::mpg |>
  ggcascade(
    all = TRUE,
    recent = year > 2000,
    "recent & economic" = year > 2000 & displ < 3,
    .by = pick(cyl, drv),
    .add_n = FALSE,
    .text_size = 2
  )
```

ggcoef_model *Plot model coefficients*

Description

ggcoef_model(), ggcoef_table(), ggcoef_multinom(), ggcoef_multicomponents() and ggcoef_compare() use broom.helpers::tidy_plus_plus() to obtain a tibble of the model coefficients, apply additional data transformation and then pass the produced tibble to ggcoef_plot() to generate the plot.

Usage

```
ggcoef_model(
  model,
  tidy_fun = broom.helpers::tidy_with_broom_or_parameters,
  tidy_args = NULL,
  conf.int = TRUE,
  conf.level = 0.95,
  exponentiate = FALSE,
  variable_labels = NULL,
  term_labels = NULL,
  interaction_sep = " * ",
  categorical_terms_pattern = "{level}",
  add_reference_rows = TRUE,
  no_reference_row = NULL,
  intercept = FALSE,
  include = dplyr::everything(),
  add_pairwise_contrasts = FALSE,
  pairwise_variables = broom.helpers::all_categorical(),
  keep_model_terms = FALSE,
  pairwise_reverse = TRUE,
  emmeans_args = list(),
  significance = 1 - conf.level,
  significance_labels = NULL,
  show_p_values = TRUE,
  signif_stars = TRUE,
  return_data = FALSE,
  ...
)

ggcoef_table(
  model,
  tidy_fun = broom.helpers::tidy_with_broom_or_parameters,
  tidy_args = NULL,
  conf.int = TRUE,
  conf.level = 0.95,
  exponentiate = FALSE,
```

```
  variable_labels = NULL,
  term_labels = NULL,
  interaction_sep = " * ",
  categorical_terms_pattern = "{level}",
  add_reference_rows = TRUE,
  no_reference_row = NULL,
  intercept = FALSE,
  include = dplyr::everything(),
  add_pairwise_contrasts = FALSE,
  pairwise_variables = broom.helpers::all_categorical(),
  keep_model_terms = FALSE,
  pairwise_reverse = TRUE,
  emmeans_args = list(),
  significance = 1 - conf.level,
  significance_labels = NULL,
  show_p_values = FALSE,
  signif_stars = FALSE,
  table_stat = c("estimate", "ci", "p.value"),
  table_header = NULL,
  table_text_size = 3,
  table_stat_label = NULL,
  ci_pattern = "{conf.low}, {conf.high}",
  table_witdhs = c(3, 2),
  plot_title = NULL,
  ...
)

ggcoef_compare(
  models,
  type = c("dodged", "faceted"),
  tidy_fun = broom.helpers::tidy_with_broom_or_parameters,
  tidy_args = NULL,
  conf.int = TRUE,
  conf.level = 0.95,
  exponentiate = FALSE,
  variable_labels = NULL,
  term_labels = NULL,
  interaction_sep = " * ",
  categorical_terms_pattern = "{level}",
  add_reference_rows = TRUE,
  no_reference_row = NULL,
  intercept = FALSE,
  include = dplyr::everything(),
  add_pairwise_contrasts = FALSE,
  pairwise_variables = broom.helpers::all_categorical(),
  keep_model_terms = FALSE,
  pairwise_reverse = TRUE,
  emmeans_args = list(),
```

```
  significance = 1 - conf.level,
  significance_labels = NULL,
  return_data = FALSE,
  ...
)

ggcoef_multinom(
  model,
  type = c("dodged", "faceted", "table"),
  y.level_label = NULL,
  tidy_fun = broom.helpers::tidy_with_broom_or_parameters,
  tidy_args = NULL,

  table_header = NULL,
  table_text_size = 3,
  table_stat_label = NULL,
  ci_pattern = "{conf.low}, {conf.high}",
  table_witdhs = c(3, 2),
  ...
)

ggcoef_plot(
  data,
  x = "estimate",
  y = "label",
  exponentiate = FALSE,
  point_size = 2,
  point_stroke = 2,
  point_fill = "white",
  colour = NULL,
  colour_guide = TRUE,
  colour_lab = "",
  colour_labels = ggplot2::waiver(),
  shape = "significance",
  shape_values = c(16, 21),
  shape_guide = TRUE,
  shape_lab = "",
  errorbar = TRUE,
  errorbar_height = 0.1,
  errorbar_coloured = FALSE,
  stripped_rows = TRUE,
  strips_odd = "#11111111",
  strips_even = "#00000000",
  vline = TRUE,
  vline_colour = "grey50",
  dodged = FALSE,
  dodged_width = 0.8,
  facet_row = "var_label",
  facet_col = NULL,
  facet_labeller = "label_value"
)
```

Arguments

model	a regression model object
tidy_fun	(function) Option to specify a custom tidier function.
tidy_args	Additional arguments passed to broom.helpers::tidy_plus_plus() and to tidy_fun
conf.int	(logical) Should confidence intervals be computed? (see broom::tidy())
conf.level	the confidence level to use for the confidence interval if conf.int = TRUE; must be strictly greater than 0 and less than 1; defaults to 0.95, which corresponds to a 95 percent confidence interval
exponentiate	if TRUE a logarithmic scale will be used for x-axis
variable_labels	(formula-list-selector) A named list or a named vector of custom variable labels.
term_labels	(list or vector) A named list or a named vector of custom term labels.
interaction_sep	(string) Separator for interaction terms.
categorical_terms_pattern	(glue pattern) A glue pattern for labels of categorical terms with treatment or sum contrasts (see model_list_terms_levels()).
add_reference_rows	(logical) Should reference rows be added?
no_reference_row	(tidy-select) Variables for those no reference row should be added, when add_reference_rows = TRUE.
intercept	(logical) Should the intercept(s) be included?
include	(tidy-select) Variables to include. Default is everything(). See also all_continuous(), all_categorical(), all_dichotomous() and all_interaction().
add_pairwise_contrasts	(logical) Apply tidy_add_pairwise_contrasts()?
pairwise_variables	(tidy-select) Variables to add pairwise contrasts.
keep_model_terms	(logical) Keep original model terms for variables where pairwise contrasts are added? (default is FALSE)

pairwise_reverse
: (logical)
Determines whether to use "pairwise" (if TRUE) or "revpairwise" (if FALSE), see emmeans::contrast().

emmeans_args
: (list)
List of additional parameter to pass to emmeans::emmeans() when computing pairwise contrasts.

significance
: level (between 0 and 1) below which a coefficient is consider to be significantly different from 0 (or 1 if exponentiate = TRUE), NULL for not highlighting such coefficients

significance_labels
: optional vector with custom labels for significance variable

show_p_values
: if TRUE, add p-value to labels

signif_stars
: if TRUE, add significant stars to labels

return_data
: if TRUE, will return the data.frame used for plotting instead of the plot

...
: parameters passed to ggcoef_plot()

table_stat
: statistics to display in the table, use any column name returned by the tidier or "ci" for confidence intervals formatted according to ci_pattern

table_header
: optional custom headers for the table

table_text_size
: text size for the table

table_stat_label
: optional named list of labeller functions for the displayed statistic (see examples)

ci_pattern
: glue pattern for confidence intervals in the table

table_witdhs
: relative widths of the forest plot and the coefficients table

plot_title
: an optional plot title

models
: named list of models

type
: a dodged plot, a faceted plot or multiple table plots?

y.level_label
: an optional named vector for labeling y.level (see examples)

component_col
: name of the component column

component_label
: an optional named vector for labeling components

data
: a data frame containing data to be plotted, typically the output of ggcoef_model(), ggcoef_compare() or ggcoef_multinom() with the option return_data = TRUE

x, y
: variables mapped to x and y axis

point_size
: size of the points

point_stroke
: thickness of the points

point_fill
: fill colour for the points

colour
: optional variable name to be mapped to colour aesthetic

colour_guide
: should colour guide be displayed in the legend?

colour_lab
: label of the colour aesthetic in the legend

colour_labels	labels argument passed to ggplot2::scale_colour_discrete() and ggplot2::discrete_scale()
shape	optional variable name to be mapped to the shape aesthetic
shape_values	values of the different shapes to use in ggplot2::scale_shape_manual()
shape_guide	should shape guide be displayed in the legend?
shape_lab	label of the shape aesthetic in the legend
errorbar	should error bars be plotted?
errorbar_height	height of error bars
errorbar_coloured	should error bars be colored as the points?
stripped_rows	should stripped rows be displayed in the background?
strips_odd	color of the odd rows
strips_even	color of the even rows
vline	should a vertical line be drawn at 0 (or 1 if exponentiate = TRUE)?
vline_colour	colour of vertical line
dodged	should points be dodged (according to the colour aesthetic)?
dodged_width	width value for ggplot2::position_dodge()
facet_row	variable name to be used for row facets
facet_col	optional variable name to be used for column facets
facet_labeller	labeller function to be used for labeling facets; if labels are too long, you can use ggplot2::label_wrap_gen() (see examples), more information in the documentation of ggplot2::facet_grid()

Details

For more control, you can use the argument return_data = TRUE to get the produced tibble, apply any transformation of your own and then pass your customized tibble to ggcoef_plot().

Value

A ggplot2 plot or a tibble if return_data = TRUE.

Functions

- ggcoef_table(): a variation of ggcoef_model() adding a table with estimates, confidence intervals and p-values
- ggcoef_compare(): designed for displaying several models on the same plot.
- ggcoef_multinom(): a variation of ggcoef_model() adapted to multinomial logistic regressions performed with nnet::multinom().
- ggcoef_multicomponents(): a variation of ggcoef_model() adapted to multi-component models such as zero-inflated models or beta regressions. ggcoef_multicomponents() has been tested with pscl::zeroinfl(), pscl::hurdle() and betareg::betareg()
- ggcoef_plot(): plot a tidy tibble of coefficients

```

`gglikert` *Plotting Likert-type items*

Description

Combines several factor variables using the same list of ordered levels (e.g. Likert-type scales) into a unique data frame and generates a centered bar plot.

Usage

```
gglikert(
  data,
  include = dplyr::everything(),
  weights = NULL,
  y = ".question",
```

```
  variable_labels = NULL,
  sort = c("none", "ascending", "descending"),
  sort_method = c("prop", "prop_lower", "mean", "median"),
  sort_prop_include_center = totals_include_center,
  factor_to_sort = ".question",
  exclude_fill_values = NULL,
  cutoff = NULL,
  data_fun = NULL,
  add_labels = TRUE,
  labels_size = 3.5,
  labels_color = "auto",
  labels_accuracy = 1,
  labels_hide_below = 0.05,
  add_totals = TRUE,
  totals_size = labels_size,
  totals_color = "black",
  totals_accuracy = labels_accuracy,
  totals_fontface = "bold",
  totals_include_center = FALSE,
  totals_hjust = 0.1,
  y_reverse = TRUE,
  y_label_wrap = 50,
  reverse_likert = FALSE,
  width = 0.9,
  facet_rows = NULL,
  facet_cols = NULL,
  facet_label_wrap = 50,
  symmetric = FALSE
)

gglikert_data(
  data,
  include = dplyr::everything(),
  weights = NULL,
  variable_labels = NULL,
  sort = c("none", "ascending", "descending"),
  sort_method = c("prop", "prop_lower", "mean", "median"),
  sort_prop_include_center = TRUE,
  factor_to_sort = ".question",
  exclude_fill_values = NULL,
  cutoff = NULL,
  data_fun = NULL
)

gglikert_stacked(
  data,
  include = dplyr::everything(),
  weights = NULL,
```

```
  y = ".question",
  variable_labels = NULL,
  sort = c("none", "ascending", "descending"),
  sort_method = c("prop", "prop_lower", "mean", "median"),
  sort_prop_include_center = FALSE,
  factor_to_sort = ".question",
  data_fun = NULL,
  add_labels = TRUE,
  labels_size = 3.5,
  labels_color = "auto",
  labels_accuracy = 1,
  labels_hide_below = 0.05,
  add_median_line = FALSE,
  y_reverse = TRUE,
  y_label_wrap = 50,
  reverse_fill = TRUE,
  width = 0.9
)
```

Arguments

`data`	a data frame
`include`	variables to include, accepts tidy-select syntax
`weights`	optional variable name of a weighting variable, accepts tidy-select syntax
`y`	name of the variable to be plotted on y axis (relevant when `.question` is mapped to "facets, see examples), accepts tidy-select syntax
`variable_labels`	a named list or a named vector of custom variable labels
`sort`	should the factor defined by `factor_to_sort` be sorted according to the answers (see `sort_method`)? One of "none" (default), "ascending" or "descending"
`sort_method`	method used to sort the variables: `"prop"` sort according to the proportion of answers higher than the centered level, `"prop_lower"` according to the proportion lower than the centered level, `"mean"` considers answer as a score and sort according to the mean score, `"median"` used the median and the majority judgment rule for tie-breaking.
`sort_prop_include_center`	when sorting with `"prop"` and if the number of levels is uneven, should half of the central level be taken into account to compute the proportion?
`factor_to_sort`	name of the factor column to sort if `sort` is not equal to `"none"`; by default the list of questions passed to `include`; should be one factor column of the tibble returned by `gglikert_data()`; accepts tidy-select syntax
`exclude_fill_values`	Vector of values that should not be displayed (but still taken into account for computing proportions), see `position_likert()`

`cutoff` number of categories to be displayed negatively (i.e. on the left of the x axis or the bottom of the y axis), could be a decimal value: `2` to display negatively the two first categories, `2.5` to display negatively the two first categories and half of the third, `2.2` to display negatively the two first categories and a fifth of the third (see examples). By default (`NULL`), it will be equal to the number of categories divided by 2, i.e. it will be centered.

`data_fun` for advanced usage, custom function to be applied to the generated dataset at the end of `gglikert_data()`

`add_labels` should percentage labels be added to the plot?

`labels_size` size of the percentage labels

`labels_color` color of the percentage labels (`"auto"` to use `hex_bw()` to determine a font color based on background color)

`labels_accuracy` accuracy of the percentages, see `scales::label_percent()`

`labels_hide_below` if provided, values below will be masked, see `label_percent_abs()`

`add_totals` should the total proportions of negative and positive answers be added to plot? **This option is not compatible with facets!**

`totals_size` size of the total proportions

`totals_color` color of the total proportions

`totals_accuracy` accuracy of the total proportions, see `scales::label_percent()`

`totals_fontface` font face of the total proportions

`totals_include_center` if the number of levels is uneven, should half of the center level be added to the total proportions?

`totals_hjust` horizontal adjustment of totals labels on the x axis

`y_reverse` should the y axis be reversed?

`y_label_wrap` number of characters per line for y axis labels, see `scales::label_wrap()`

`reverse_likert` if `TRUE`, will reverse the default stacking order, see `position_likert()`

`width` bar width, see `ggplot2::geom_bar()`

`facet_rows, facet_cols` A set of variables or expressions quoted by `ggplot2::vars()` and defining faceting groups on the rows or columns dimension (see examples)

`facet_label_wrap` number of characters per line for facet labels, see `ggplot2::label_wrap_gen()`

`symmetric` should the x-axis be symmetric?

`add_median_line` add a vertical line at 50%?

`reverse_fill` if `TRUE`, will reverse the default stacking order, see `ggplot2::position_fill()`

Details

You could use `gglikert_data()` to just produce the dataset to be plotted.

If variable labels have been defined (see `labelled::var_label()`), they will be considered. You can also pass custom variables labels with the `variable_labels` argument.

Value

A `ggplot2` plot or a `tibble`.

  facet_grid(rows = vars(.question))
```

---

ggsurvey *Easy ggplot2 with survey objects*

Description

A function to facilitate ggplot2 graphs using a survey object. It will initiate a ggplot and map survey weights to the corresponding aesthetic.

Usage

```
ggsurvey(design = NULL, mapping = NULL, ...)
```

Arguments

design	A survey design object, usually created with survey::svydesign()
mapping	Default list of aesthetic mappings to use for plot, to be created with ggplot2::aes().
...	Other arguments passed on to methods. Not currently used.

Details

Graphs will be correct as long as only weights are required to compute the graph. However, statistic or geometry requiring correct variance computation (like ggplot2::geom_smooth()) will be statistically incorrect.

Value

A ggplot2 plot.

Examples

```
data(api, package = "survey")
dstrat <- survey::svydesign(
  id = ~1, strata = ~stype,
  weights = ~pw, data = apistrat,
  fpc = ~fpc
)
ggsurvey(dstrat) +
```

```
  ggplot2::aes(x = cnum, y = dnum) +
  ggplot2::geom_count()

d <- as.data.frame(Titanic)
dw <- survey::svydesign(ids = ~1, weights = ~Freq, data = d)
ggsurvey(dw) +
  ggplot2::aes(x = Class, fill = Survived) +
  ggplot2::geom_bar(position = "fill")
```

`hex_bw` *Identify a suitable font color (black or white) given a background HEX color*

Description

`hex_bw_threshold()` is a variation of `hex_bw()`. For `values` below `threshold`, black (`"#000000"`) will always be returned, regardless of `hex_code`.

Usage

```
hex_bw(hex_code)

hex_bw_threshold(hex_code, values, threshold)
```

Arguments

`hex_code`	Background color in hex-format.
`values`	Values to be compared.
`threshold`	Threshold.

Value

Either black or white, in hex-format

Source

Adapted from `saros`

Examples

```
hex_bw("#0dadfd")

library(ggplot2)
ggplot(diamonds) +
  aes(x = cut, fill = color, label = after_stat(count)) +
  geom_bar() +
  geom_text(
    mapping = aes(color = after_scale(hex_bw(.data$fill))),
```

```
  position = position_stack(.5),
  stat = "count",
  size = 2
)
```

`label_number_abs` *Label absolute values*

Description

Label absolute values

Usage

```
label_number_abs(..., hide_below = NULL)

label_percent_abs(..., hide_below = NULL)
```

Arguments

`...`	arguments passed to `scales::label_number()` or `scales::label_percent()`
`hide_below`	if provided, values below `hide_below` will be masked (i.e. an empty string `""` will be returned)

Value

A "labelling" function, , i.e. a function that takes a vector and returns a character vector of same length giving a label for each input value.

See Also

`scales::label_number()`, `scales::label_percent()`

Examples

```
x <- c(-0.2, -.05, 0, .07, .25, .66)

scales::label_number()(x)
label_number_abs()(x)

scales::label_percent()(x)
label_percent_abs()(x)
label_percent_abs(hide_below = .1)(x)
```

`pal_extender` *Extend a discrete colour palette*

Description

If the palette returns less colours than requested, the list of colours will be expanded using `scales::pal_gradient_n()`. To be used with a sequential or diverging palette. Not relevant for qualitative palettes.

Usage

```
pal_extender(pal = scales::brewer_pal(palette = "BrBG"))

scale_fill_extended(
  name = waiver(),
  ...,
  pal = scales::brewer_pal(palette = "BrBG"),
  aesthetics = "fill"
)

scale_colour_extended(
  name = waiver(),
  ...,
  pal = scales::brewer_pal(palette = "BrBG"),
  aesthetics = "colour"
)
```

Arguments

`pal`	A palette function, such as returned by scales::brewer_pal, taking a number of colours as entry and returning a list of colours.
`name`	The name of the scale. Used as the axis or legend title. If `waiver()`, the default, the name of the scale is taken from the first mapping used for that aesthetic. If `NULL`, the legend title will be omitted.
`...`	Other arguments passed on to `discrete_scale()` to control name, limits, breaks, labels and so forth.
`aesthetics`	Character string or vector of character strings listing the name(s) of the aesthetic(s) that this scale works with. This can be useful, for example, to apply colour settings to the colour and fill aesthetics at the same time, via `aesthetics = c("colour", "fill")`.

Value

A palette function.

Examples

```
pal <- scales::pal_brewer(palette = "PiYG")
scales::show_col(pal(16))
scales::show_col(pal_extender(pal)(16))
```

`position_likert` *Stack objects on top of each another and center them around 0*

Description

`position_diverging()` stacks bars on top of each other and center them around zero (the same number of categories are displayed on each side). `position_likert()` uses proportions instead of counts. This type of presentation is commonly used to display Likert-type scales.

Usage

```
position_likert(
  vjust = 1,
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL
)

position_diverging(
  vjust = 1,
  reverse = FALSE,
  exclude_fill_values = NULL,
  cutoff = NULL
)
```

Arguments

`vjust`	Vertical adjustment for geoms that have a position (like points or lines), not a dimension (like bars or areas). Set to `0` to align with the bottom, `0.5` for the middle, and `1` (the default) for the top.
`reverse`	If `TRUE`, will reverse the default stacking order. This is useful if you're rotating both the plot and legend.
`exclude_fill_values`	Vector of values from the variable associated with the `fill` aesthetic that should not be displayed (but still taken into account for computing proportions)
`cutoff`	number of categories to be displayed negatively (i.e. on the left of the x axis or the bottom of the y axis), could be a decimal value: `2` to display negatively the two first categories, `2.5` to display negatively the two first categories and half of the third, `2.2` to display negatively the two first categories and a fifth of the third (see examples). By default (`NULL`), it will be equal to the number of categories divided by 2, i.e. it will be centered.

Details

It is recommended to use `position_likert()` with `stat_prop()` and its `complete` argument (see examples).

See Also

See `ggplot2::position_stack()` and `ggplot2::position_fill()`

Examples

```
library(ggplot2)

ggplot(diamonds) +
  aes(y = clarity, fill = cut) +

  ) +
  scale_x_continuous(label = label_percent_abs()) +
  scale_fill_likert() +
  xlab("proportion")

# Do not display specific fill values ----------------------------------------
# (but taken into account to compute proportions)

ggplot(diamonds) +
  aes(y = clarity, fill = cut) +
```

```
geom_bar(position = position_likert(exclude_fill_values = "Very Good")) +
scale_x_continuous(label = label_percent_abs()) +
scale_fill_likert() +
xlab("proportion")
```

---

round_any *Round to multiple of any number.*

Description

Round to multiple of any number.

Usage

```
round_any(x, accuracy, f = round)
```

Arguments

x	numeric or date-time (POSIXct) vector to round
accuracy	number to round to; for POSIXct objects, a number of seconds
f	rounding function: floor, ceiling or round

Source

adapted from plyr

Examples

```
round_any(1.865, accuracy = .25)
```

---

scale_fill_likert *Colour scale for Likert-type plots*

Description

This scale is similar to other diverging discrete colour scales, but allows to change the "center" of the scale using cutoff argument, as used by position_likert().

Usage

```
scale_fill_likert(
  name = waiver(),
  ...,
  pal = scales::brewer_pal(palette = "BrBG"),
  cutoff = NULL,
  aesthetics = "fill"
)

likert_pal(pal = scales::brewer_pal(palette = "BrBG"), cutoff = NULL)
```

Arguments

name	The name of the scale. Used as the axis or legend title. If `waiver()`, the default, the name of the scale is taken from the first mapping used for that aesthetic. If `NULL`, the legend title will be omitted.
...	Other arguments passed on to `discrete_scale()` to control name, limits, breaks, labels and so forth.
pal	A palette function taking a number of colours as entry and returning a list of colours (see examples), ideally a diverging palette
cutoff	Number of categories displayed negatively (see `position_likert()`) and therefore changing the center of the colour scale (see examples).
aesthetics	Character string or vector of character strings listing the name(s) of the aesthetic(s) that this scale works with. This can be useful, for example, to apply colour settings to the colour and fill aesthetics at the same time, via `aesthetics = c("colour", "fill")`.

Examples

```
library(ggplot2)
ggplot(diamonds) +
  aes(y = clarity, fill = cut) +
  geom_bar(position = "likert") +
  scale_x_continuous(label = label_percent_abs()) +
  xlab("proportion")

ggplot(diamonds) +
  aes(y = clarity, fill = cut) +
  geom_bar(position = "likert") +
  scale_x_continuous(label = label_percent_abs()) +
  xlab("proportion") +
  scale_fill_likert()

 ggplot(diamonds) +
  aes(y = clarity, fill = cut) +
  geom_bar(position = position_likert(cutoff = 1)) +
  scale_x_continuous(label = label_percent_abs()) +
  xlab("proportion") +
  scale_fill_likert(cutoff = 1)
```

signif_stars *Significance Stars*

Description

Calculate significance stars

Usage

```
signif_stars(x, three = 0.001, two = 0.01, one = 0.05, point = 0.1)
```

Arguments

x	numeric values that will be compared to the point, one, two, and three values
three	threshold below which to display three stars
two	threshold below which to display two stars
one	threshold below which to display one star
point	threshold below which to display one point (NULL to deactivate)

Value

Character vector containing the appropriate number of stars for each x value.

Author(s)

Joseph Larmarange

Examples

```
x <- c(0.5, 0.1, 0.05, 0.01, 0.001)
signif_stars(x)
signif_stars(x, one = .15, point = NULL)
```

stat_cross *Compute cross-tabulation statistics*

Description

Computes statistics of a 2-dimensional matrix using broom::augment.htest.

Usage

```
stat_cross(
  mapping = NULL,
  data = NULL,
  geom = "point",
  position = "identity",
  ...,
  na.rm = TRUE,
  show.legend = NA,
  inherit.aes = TRUE,
  keep.zero.cells = FALSE
)
```

Arguments

mapping	Set of aesthetic mappings created by aes(). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options: If NULL, the default, the data is inherited from the plot data as specified in the call to ggplot(). A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See fortify() for which variables will be created. A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x, 10)).
geom	Override the default connection with ggplot2::geom_point().
position	A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The position argument accepts the following: • The result of calling a position function, such as position_jitter(). This method allows for passing extra arguments to the position. • A string naming the position adjustment. To give the position as a string, strip the function name of the position_ prefix. For example, to use position_jitter(), give the position as "jitter". • For more information and other ways to specify the position, see the layer position documentation.
...	Other arguments passed on to layer()'s params argument. These arguments broadly fall into one of 4 categories below. Notably, further arguments to the position argument, or aesthetics that are required can *not* be passed through .... Unknown arguments that are not part of the 4 categories below are ignored. • Static aesthetics that are not mapped to a scale, but are at a fixed value and apply to the layer as a whole. For example, colour = "red" or linewidth = 3. The geom's documentation has an **Aesthetics** section that lists the available options. The 'required' aesthetics cannot be passed on to the

params. Please note that while passing unmapped aesthetics as vectors is technically possible, the order and required length is not guaranteed to be parallel to the input data.

- When constructing a layer using a `stat_*()` function, the `...` argument can be used to pass on parameters to the geom part of the layer. An example of this is `stat_density(geom = "area", outline.type = "both")`. The geom's documentation lists which parameters it can accept.
- Inversely, when constructing a layer using a `geom_*()` function, the `...` argument can be used to pass on parameters to the `stat` part of the layer. An example of this is `geom_area(stat = "density", adjust = 0.5)`. The stat's documentation lists which parameters it can accept.
- The `key_glyph` argument of `layer()` may also be passed on through `....` This can be one of the functions described as key glyphs, to change the display of the layer in the legend.

`na.rm` If `TRUE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.

`show.legend` logical. Should this layer be included in the legends? `NA`, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes. It can also be a named logical vector to finely select the aesthetics to display.

`inherit.aes` If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. `borders()`.

`keep.zero.cells`
If `TRUE`, cells with no observations are kept.

Value

A `ggplot2` plot with the added statistic.

Aesthetics

`stat_cross()` requires the **x** and the **y** aesthetics.

Computed variables

observed number of observations in x,y

prop proportion of total

row.prop row proportion

col.prop column proportion

expected expected count under the null hypothesis

resid Pearson's residual

std.resid standardized residual

row.observed total number of observations within row

col.observed total number of observations within column

total.observed total number of observations within the table

phi phi coefficients, see `augment_chisq_add_phi()`

  facet_grid(Sex ~ .) +
  labs(fill = "Standardized residuals") +
  theme_minimal()
```

---

stat_prop *Compute proportions according to custom denominator*

Description

stat_prop() is a variation of ggplot2::stat_count() allowing to compute custom proportions according to the **by** aesthetic defining the denominator (i.e. all proportions for a same value of **by** will sum to 1). If the **by** aesthetic is not specified, denominators will be determined according to the default_by argument.

Usage

```
stat_prop(
  mapping = NULL,
  data = NULL,
  geom = "bar",
  position = "fill",
  ...,
  width = NULL,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE,
  complete = NULL,
  default_by = "total",
  height = c("count", "prop"),
  labels = c("prop", "count"),
  labeller = scales::label_percent(accuracy = 0.1)
)

geom_prop_bar(
  mapping = NULL,
  data = NULL,
  stat = "prop",
  position = position_stack(),
  ...,
  complete = NULL,
  default_by = "x",
  height = "prop"
)
```

```
geom_prop_text(
  mapping = NULL,
  data = NULL,
  stat = "prop",
  position = position_stack(vjust),
  ...,
  complete = NULL,
  default_by = "x",
  height = "prop",
  labels = "prop",
  labeller = scales::label_percent(accuracy = 0.1),
  vjust = 0.5
)
```

Arguments

mapping	Set of aesthetic mappings created by aes(). If specified and inherit.aes = TRUE (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.
data	The data to be displayed in this layer. There are three options: If NULL, the default, the data is inherited from the plot data as specified in the call to ggplot(). A data.frame, or other object, will override the plot data. All objects will be fortified to produce a data frame. See fortify() for which variables will be created. A function will be called with a single argument, the plot data. The return value must be a data.frame, and will be used as the layer data. A function can be created from a formula (e.g. ~ head(.x, 10)).
geom	Override the default connection with ggplot2::geom_bar().
position	A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The position argument accepts the following: • The result of calling a position function, such as position_jitter(). This method allows for passing extra arguments to the position. • A string naming the position adjustment. To give the position as a string, strip the function name of the position_ prefix. For example, to use position_jitter(), give the position as "jitter". • For more information and other ways to specify the position, see the layer position documentation.
...	Other arguments passed on to layer()'s params argument. These arguments broadly fall into one of 4 categories below. Notably, further arguments to the position argument, or aesthetics that are required can *not* be passed through .... Unknown arguments that are not part of the 4 categories below are ignored. • Static aesthetics that are not mapped to a scale, but are at a fixed value and apply to the layer as a whole. For example, colour = "red" or linewidth = 3. The geom's documentation has an **Aesthetics** section that lists the

available options. The 'required' aesthetics cannot be passed on to the params. Please note that while passing unmapped aesthetics as vectors is technically possible, the order and required length is not guaranteed to be parallel to the input data.

- When constructing a layer using a stat_*() function, the ... argument can be used to pass on parameters to the geom part of the layer. An example of this is stat_density(geom = "area", outline.type = "both"). The geom's documentation lists which parameters it can accept.
- Inversely, when constructing a layer using a geom_*() function, the ... argument can be used to pass on parameters to the stat part of the layer. An example of this is geom_area(stat = "density", adjust = 0.5). The stat's documentation lists which parameters it can accept.
- The key_glyph argument of layer() may also be passed on through .... This can be one of the functions described as key glyphs, to change the display of the layer in the legend.

width — Bar width. By default, set to 90% of the resolution() of the data.

na.rm — If FALSE, the default, missing values are removed with a warning. If TRUE, missing values are silently removed.

orientation — The orientation of the layer. The default (NA) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be given explicitly by setting orientation to either "x" or "y". See the *Orientation* section for more detail.

show.legend — logical. Should this layer be included in the legends? NA, the default, includes if any aesthetics are mapped. FALSE never includes, and TRUE always includes. It can also be a named logical vector to finely select the aesthetics to display.

inherit.aes — If FALSE, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. borders().

complete — Name (character) of an aesthetic for those statistics should be completed for unobserved values (see example).

default_by — If the **by** aesthetic is not available, name of another aesthetic that will be used to determine the denominators (e.g. "fill"), or NULL or "total" to compute proportions of the total. To be noted, default_by = "x" works both for vertical and horizontal bars.

height — Which statistic ("count" or "prop") should be used, by default, for determining the height/width of the geometry (accessible through after_stat(height))?

labels — Which statistic ("prop" or "count") should be used, by default, for generating formatted labels (accessible through after_stat(labels))?

labeller — Labeller function to format labels and populate after_stat(labels).

stat — The statistical transformation to use on the data for this layer.

vjust — Vertical/Horizontal adjustment for the position. Set to 0 to align with the bottom/left, 0.5 (the default) for the middle, and 1 for the top/right.

Value

A ggplot2 plot with the added statistic.

Aesthetics

`stat_prop()` understands the following aesthetics (required aesthetics are in bold):

- **x *or* y**
- by
- weight

Computed variables

`after_stat(count)` number of points in bin

`after_stat(denominator)` denominator for the proportions

`after_stat(prop)` computed proportion, i.e. `after_stat(count)/after_stat(denominator)`

`after_stat(height)` counts or proportions, according to `height`

`after_stat(labels)` formatted heights, according to `labels` and `labeller`

See Also

Examples

```
library(ggplot2)
d <- as.data.frame(Titanic)

p <- ggplot(d) +
  aes(x = Class, fill = Survived, weight = Freq, by = Class) +
  geom_bar(position = "fill") +
  geom_text(stat = "prop", position = position_fill(.5))
p
p + facet_grid(~Sex)

ggplot(d) +
  aes(x = Class, fill = Survived, weight = Freq) +
  geom_bar(position = "dodge") +
  geom_text(
    aes(by = Survived),
    stat = "prop",
    position = position_dodge(0.9), vjust = "bottom"
  )

if (requireNamespace("scales")) {
  ggplot(d) +
    aes(x = Class, fill = Survived, weight = Freq, by = 1) +
    geom_bar() +
    geom_text(
      aes(label = scales::percent(after_stat(prop), accuracy = 1)),
      stat = "prop",
      position = position_stack(.5)
```

```
    )
}

ggplot(d) +
aes(y = Class, fill = Survived, weight = Freq) +
  geom_prop_bar() +
  geom_prop_text()

# displaying unobserved levels with complete
d <- diamonds |>
  dplyr::filter(!(cut == "Ideal" & clarity == "I1")) |>
  dplyr::filter(!(cut == "Very Good" & clarity == "VS2")) |>
  dplyr::filter(!(cut == "Premium" & clarity == "IF"))
p <- ggplot(d) +
  aes(x = clarity, fill = cut, by = clarity) +
  geom_bar(position = "fill")
p + geom_text(stat = "prop", position = position_fill(.5))
p + geom_text(stat = "prop", position = position_fill(.5), complete = "fill")
```

`stat_weighted_mean` *Compute weighted y mean*

Description

This statistic will compute the mean of **y** aesthetic for each unique value of **x**, taking into account **weight** aesthetic if provided.

Usage

```
stat_weighted_mean(
  mapping = NULL,
  data = NULL,
  geom = "point",
  position = "identity",
  ...,
  na.rm = FALSE,
  orientation = NA,
  show.legend = NA,
  inherit.aes = TRUE
)
```

Arguments

`mapping`	Set of aesthetic mappings created by `aes()`. If specified and `inherit.aes = TRUE` (the default), it is combined with the default mapping at the top level of the plot. You must supply `mapping` if there is no plot mapping.

`data` The data to be displayed in this layer. There are three options:

If `NULL`, the default, the data is inherited from the plot data as specified in the call to `ggplot()`.

A `data.frame`, or other object, will override the plot data. All objects will be fortified to produce a data frame. See `fortify()` for which variables will be created.

A `function` will be called with a single argument, the plot data. The return value must be a `data.frame`, and will be used as the layer data. A `function` can be created from a `formula` (e.g. `~ head(.x, 10)`).

`geom` Override the default connection with `ggplot2::geom_point()`.

`position` A position adjustment to use on the data for this layer. This can be used in various ways, including to prevent overplotting and improving the display. The `position` argument accepts the following:

- The result of calling a position function, such as `position_jitter()`. This method allows for passing extra arguments to the position.
- A string naming the position adjustment. To give the position as a string, strip the function name of the `position_` prefix. For example, to use `position_jitter()`, give the position as `"jitter"`.
- For more information and other ways to specify the position, see the layer position documentation.

`...` Other arguments passed on to `layer()`'s `params` argument. These arguments broadly fall into one of 4 categories below. Notably, further arguments to the `position` argument, or aesthetics that are required can *not* be passed through `...`. Unknown arguments that are not part of the 4 categories below are ignored.

- Static aesthetics that are not mapped to a scale, but are at a fixed value and apply to the layer as a whole. For example, `colour = "red"` or `linewidth = 3`. The geom's documentation has an **Aesthetics** section that lists the available options. The 'required' aesthetics cannot be passed on to the `params`. Please note that while passing unmapped aesthetics as vectors is technically possible, the order and required length is not guaranteed to be parallel to the input data.
- When constructing a layer using a `stat_*()` function, the `...` argument can be used to pass on parameters to the `geom` part of the layer. An example of this is `stat_density(geom = "area", outline.type = "both")`. The geom's documentation lists which parameters it can accept.
- Inversely, when constructing a layer using a `geom_*()` function, the `...` argument can be used to pass on parameters to the `stat` part of the layer. An example of this is `geom_area(stat = "density", adjust = 0.5)`. The stat's documentation lists which parameters it can accept.
- The `key_glyph` argument of `layer()` may also be passed on through `...`. This can be one of the functions described as key glyphs, to change the display of the layer in the legend.

`na.rm` If `FALSE`, the default, missing values are removed with a warning. If `TRUE`, missing values are silently removed.

`orientation` The orientation of the layer. The default (`NA`) automatically determines the orientation from the aesthetic mapping. In the rare event that this fails it can be

given explicitly by setting `orientation` to either `"x"` or `"y"`. See the *Orientation* section for more detail.

`show.legend` logical. Should this layer be included in the legends? `NA`, the default, includes if any aesthetics are mapped. `FALSE` never includes, and `TRUE` always includes. It can also be a named logical vector to finely select the aesthetics to display.

`inherit.aes` If `FALSE`, overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. `borders()`.

Value

A `ggplot2` plot with the added statistic.

Computed variables

y weighted y (numerator / denominator)

numerator numerator

denominator denominator

`vignette("stat_weighted_mean")`

Examples

```
library(ggplot2)

data(tips, package = "reshape")

ggplot(tips) +
  aes(x = day, y = total_bill) +
  geom_point()

ggplot(tips) +
  aes(x = day, y = total_bill) +
  stat_weighted_mean()

ggplot(tips) +
  aes(x = day, y = total_bill, group = 1) +
  stat_weighted_mean(geom = "line")

ggplot(tips) +
  aes(x = day, y = total_bill, colour = sex, group = sex) +
  stat_weighted_mean(geom = "line")

ggplot(tips) +
  aes(x = day, y = total_bill, fill = sex) +
  stat_weighted_mean(geom = "bar", position = "dodge")
```

```
# computing a proportion on the fly
if (requireNamespace("scales")) {
  ggplot(tips) +
    aes(x = day, y = as.integer(smoker == "Yes"), fill = sex) +
    stat_weighted_mean(geom = "bar", position = "dodge") +
    scale_y_continuous(labels = scales::percent)
}

library(ggplot2)

# taking into account some weights
if (requireNamespace("scales")) {
  d <- as.data.frame(Titanic)
  ggplot(d) +
    aes(
      x = Class, y = as.integer(Survived == "Yes"),
      weight = Freq, fill = Sex
    ) +
    geom_bar(stat = "weighted_mean", position = "dodge") +
    scale_y_continuous(labels = scales::percent) +
    labs(y = "Survived")
}
```

`symmetric_limits` *Symmetric limits*

Description

Expand scale limits to make them symmetric around zero. Can be passed as argument to parameter `limits` of continuous scales from packages {ggplot2} or {scales}. Can be also used to obtain an enclosing symmetric range for numeric vectors.

Usage

```
symmetric_limits(x)
```

Arguments

x	a vector of numeric values, possibly a range, from which to compute enclosing range

Value

A numeric vector of length two with the new limits, which are always such that the absolute value of upper and lower limits is the same.

Source

Adapted from the homonym function in {ggpmisc}

Examples

```
library(ggplot2)

ggplot(iris) +
  aes(x = Sepal.Length - 5, y = Sepal.Width - 3, colour = Species) +
  geom_vline(xintercept = 0) +
  geom_hline(yintercept = 0) +
  geom_point()

last_plot() +
  scale_x_continuous(limits = symmetric_limits) +
  scale_y_continuous(limits = symmetric_limits)
```

---

weighted.median *Weighted Median and Quantiles*

Description

Compute the median or quantiles a set of numbers which have weights associated with them.

Usage

```
weighted.median(x, w, na.rm = TRUE, type = 2)

weighted.quantile(x, w, probs = seq(0, 1, 0.25), na.rm = TRUE, type = 4)
```

Arguments

x	a numeric vector of values
w	a numeric vector of weights
na.rm	a logical indicating whether to ignore NA values
type	Integer specifying the rule for calculating the median or quantile, corresponding to the rules available for stats:quantile(). The only valid choices are type=1, 2 or 4. See Details.
probs	probabilities for which the quantiles should be computed, a numeric vector of values between 0 and 1

Details

The ith observation x[i] is treated as having a weight proportional to w[i].

The weighted median is a value m such that the total weight of data less than or equal to m is equal to half the total weight. More generally, the weighted quantile with probability p is a value q such that the total weight of data less than or equal to q is equal to p times the total weight.

If there is no such value, then

- if type = 1, the next largest value is returned (this is the right-continuous inverse of the left-continuous cumulative distribution function);

- if type = 2, the average of the two surrounding values is returned (the average of the right-continuous and left-continuous inverses);
- if type = 4, linear interpolation is performed.

Note that the default rule for weighted.median() is type = 2, consistent with the traditional definition of the median, while the default for weighted.quantile() is type = 4.

Value

A numeric vector.

Source

These functions are adapted from their homonyms developed by Adrian Baddeley in the spatstat package.

Examples

```
x <- 1:20
w <- runif(20)
weighted.median(x, w)
weighted.quantile(x, w)
```

---

weighted.sum *Weighted Sum*

Description

Weighted Sum

Usage

```
weighted.sum(x, w, na.rm = TRUE)
```

Arguments

x	a numeric vector of values
w	a numeric vector of weights
na.rm	a logical indicating whether to ignore NA values

Value

A numeric vector.

Examples

```
x <- 1:20
w <- runif(20)
weighted.sum(x, w)
```
