

Package ‘munsellinterpol’

January 19, 2025

Type Package

Title Interpolate Munsell Renotation Data from Hue Value/Chroma to CIE/RGB

Version 3.1-0

Encoding UTF-8

Date 2025-01-19

Description

Methods for interpolating data in the Munsell color system following the ASTM D-1535 standard. Hues and chromas with decimal values can be interpolated and converted to/from the Munsell color system and CIE xyY, CIE XYZ, CIE Lab, CIE Luv, or RGB. Includes ISCC-NBS color block lookup. Based on the work by Paul Centore, ``The Munsell and Kubelka-Munk Toolbox".

License GPL (≥ 3)

CentroidsISCCNBS

Centroid Notations for the Revised ISCC-NBS Color-Name Blocks

Description

CentroidsISCCNBS is a table with the centroids of the revised ISCC-NBS Color-Name Blocks, taken from *Kelly (1958)*

Format

This data . frame has 267 rows and these columns:

Number ISCC-NBS number (an integer from 1 to 267)

Name ISCC-NBS name

MunsellSpec Munsell specification of the centroid of the block a (character string)

Details

The earliest paper I am aware of is by *Nickerson, et. al.* in 1941. After the big Munsell renotation in 1943, the name blocks were revised in 1955.

When the central colors were recomputed in *Kelly (1958)*, they were called the "Central Colors", though the text makes it clear that most are truly centroids, which were computed from the centroid of an "elementary shape", which is a "sector of a right cylindrical annulus". For the "peripheral blocks" of high chroma, the centroids were "estimated graphically by plotting the MacAdam limits". In *Kelly (1965)* these were called "centroid colors", and that is the name we will use here.

ColorBlockFromMunsell *Get ISCC-NBS Number and ISCC-NBS Name from Munsell HVC or Munsell Notation*

Description

Get ISCC-NBS Number and ISCC-NBS Name from Munsell HVC or Munsell Notation.

Usage

```
ColorBlockFromMunsell( MunsellSpec )
```

Arguments

MunsellSpec a numeric Nx3 matrix or a vector that can be converted to such a matrix. Each row has Munsell HVC, where H is Hue Number, and V and C are the standard Munsell Value and Chroma. The Hue is automatically wrapped to the interval (0,100]. MunsellSpec can also be a character N-vector with standard Munsell notation; it is converted to an Nx3 matrix.

Details

The ISCC-NBS System is a partition of Munsell Color Solid into 267 color blocks. Each block is a disjoint union of *elementary blocks*, where an elementary block is defined by its minimum and maximum limits in Hue, Value, and Chroma. Some blocks are non-convex. The *peripheral blocks*, of which there are 120, have arbitrary large chroma and are considered semi-infinite for this function; there is no consideration of the MacAdam limits. For each query vector HVC, the function searches a private data . frame with 932 elementary blocks, for the one elementary block that contains it.

Value

a data . frame with N rows and these columns:

HVC	the input Nx3 matrix, or such a matrix converted from Munsell notation
Number	the corresponding ISCC-NBS color number - an integer from 1 to 267
Name	the corresponding ISCC-NBS color name - a character string
Centroid	the centroid of the block in Munsell Notation - a character string; see CentroidsISCCNBS

The rownames are set to the input MunsellSpec.

History

The **Munsell Book of Color** was published in 1929. The first ISCC-NBS partition, in 1939, had 319 blocks and names (including 5 neutrals). There were no block numbers. The aimpoints of the Munsell samples were thoroughly revised in 1943. The ISCC-NBS partition was revised in 1955, and this is the version used here.

Future Work

It might be useful to compute the distance from the query point to the boundary of the containing color block.

ColorlabFormatToMunsellSpec

Convert Colorlab Munsell Format to Munsell HVC

Description

Convert Colorlab Munsell Format to Munsell HVC

Usage

```
ColorlabFormatToMunsellSpec( HVCH )
```

Arguments

HVCH a numeric Nx4 matrix, or a vector that can be converted to such a matrix, by row. Each row of the matrix contains an HVCH vector.

Details

Colorlab Munsell format uses 4 numbers.

1. Hue Step, in the interval (0,10], or 0 for neutrals
2. Munsell Value, in the interval (0,10]
3. Munsell Chroma, non-negative
4. Hue Index, an integer from 1 to 10, or 0 for neutrals

Value

an Nx3 matrix, with each row an HVC vector. Value and Chroma are simply copied unchanged. The complex part is conversion of Colorlab Hue Step and Hue Index to Hue Number. For neutrals, both Hue Step and Hue Index are ignored. Invalid input values, such as a Hue Index that is not an integer from 0 to 10 (except for neutrals), are converted to NAs. The rownames of the input are copied to the output, but if these are NULL, the rownames are set to the Munsell notations.

HVCfromMunsellName *Convert Munsell Notation to numerical Munsell HVC*

Description

Convert Munsell Notation to numerical Munsell HVC

Usage

```
HVCfromMunsellName( MunsellName )
MunsellHVC( MunsellName )
HueNumberFromString( HueString )
```

Arguments

MunsellName	a character vector of length $N > 0$, where each string should be a valid Munsell notation, e.g. '2.3P 5/2.3', '9.2YR 3/6', 'N 2.3/', and 'N 4/0'. Whitespace is optional and ignored. It is OK for a neutral to end in either '/' or '/0'.
HueString	a character vector of length $N > 0$, where each string should be the initial hue part of a Munsell notation, e.g. '4.5GY', '2.5R', '10.3B', etc. Whitespace is optional and ignored. Neutrals, denoted by 'N', are invalid because the hue is undefined.

Value

HVCfromMunsellName() returns a numeric $N \times 3$ matrix with HVC in the rows. For neutral colors, both H and C are set to 0. If a string cannot be parsed, the entire row is set to NAs. The rownames are set to MunsellName.

MunsellHVC() returns a character $N \times 3$ matrix with HVC in the rows, and is there for backward compatibility with older versions of the package. For neutral colors, H is set to 'N' and C is set to '0'.

HueNumberFromString() returns the hue number H (in (0,100]). If the string cannot be parsed, or the color is neutral, the output is set to NA.

For all functions the Hue Number is wrapped to (0,100].

Note

Ever since the *Munsell Book of Color* (1929), the Munsell hue circle has been divided into 5 *principal hues* and 5 *intermediate hues*, to define a total of 10 arcs. Each of these hues has been assigned a 10-point scale, with 5 at the midpoint of the arc. Moreover, the hue "origin" has been at '10RP'. So a 100-point scale (with no letters) for the entire hue circle is obvious and trivial to construct, but I have been unable to determine the first explicit mention of such a scale. The earliest I have found is from *Nimeroff* (1968), Figures 20 and 21 on page 27.

FIGURE 20. Diagram of hue circle with Munsell hue notation.

NOTATION	BY LETTER	RP	rRP	RP-R	pR	R	yR	R-YR	rYR	YR						
	BY LETTER B	5RP	7.5RP	10RP	2.5R	5RP	7.5R	10R	2.5R	5RP						
	NUMBER	6	7	8	9	1	2	3	4	6	7	8	9	11	12	13
BY NUMBER	95	97.5	100	2.5	5	7.5	10	12.5	15							

FIGURE 21. Alternate ways of expressing Munsell hue notation.

There is a reference to *ASTM D 1535* in the **References** of *Nimeroff*, but it is not dated, and the 2 figures are not attributed to it. There was an *ASTM D 1535* in 1968 but I have not been able to locate it; it is possible that the 100-point scale first appeared in *ASTM D-1535 (1968)*, or even earlier in *ASTM D 1525-58T (1958)*.

Interestingly, in the *Atlas of the Munsell Color System (1915)* there were only 5 principal hues (with no intermediate hues) and each of the 5 arcs was assigned a 10-point scale. If the entire hue circle of 1915 were assigned a scale, it would have been a 50-point scale.

IsWithinMacAdamLimits *Test xyY Coordinates for being Inside the MacAdam Limits*

Description

Test xyY Coordinates for being Inside the MacAdam Limits for Illuminants C and D65

Usage

```
IsWithinMacAdamLimits( xyY, Illuminant='C' )
```

Arguments

- xyY** a numeric Nx3 matrix with CIE xyY coordinates in the rows, or a vector that can be converted to such a matrix, by row. The reference white is assumed to have Y=100.
- Illuminant** either 'C' or 'D65'. Partial matching is enabled, and is case-insensitive.

Details

The *MacAdam Limit* is the boundary of the *optimal color solid* (also called the *Rösch Farbkörper*), in XYZ coordinates. The optimal color solid is convex and depends on the illuminant. Points on the boundary of the solid are called *optimal colors*. It is symmetric about the midpoint of the segment joining black and white (the 50% gray point). It can be expressed as a *zonohedron* - a convex polyhedron with a special form; for details on zonohedra, see *Centore*.

For each of the 2 illuminants, a zonohedron Z is pre-computed (and stored in `sysdata.rda`). The wavelengths used are 380 to 780 nm with 5nm step (81 wavelengths). Each zonohedron has $81*80=6480$ parallelogram faces, though some of them are coplanar. Z is expressed as the intersection of 6480 halfspaces. The plane equation of each parallelogram is pre-computed, but redundant ones are not removed (in this version).

For testing a query point xyY , a pseudo-distance metric δ is used. Let the zonohedron Z be the intersection of the halfspaces $\langle h_i, x \rangle \leq b_i$ $i = 1, \dots, n$, where each h_i is a unit vector. The point xyY is converted to XYZ, and $\delta(XYZ)$ is computed as: $\delta(XYZ) := \max(\langle h_i, XYZ \rangle - b_i)$ where the maximum is taken over all $i = 1, \dots, n$. This calculation can be optimized; because the zonohedron is centrally symmetric, only half of the planes actually have to be stored, and this cuts the memory and processing time in half. It is clear that XYZ is within the zonohedron iff $\delta(XYZ) \leq 0$, and that XYZ is on the boundary iff $\delta(XYZ)=0$. This pseudo-distance is part of the returned `data.frame`.

An interesting fact is that if $\delta(XYZ)>0$, then $\delta(XYZ) \leq \text{dist}(XYZ, Z)$, with equality iff the segment from XYZ to the point z on the boundary of Z closest to XYZ is normal to one of the faces of Z that contains z . This is why we call δ a *pseudo-distance*. Another interesting fact is that if $\delta(XYZ) \leq 0$, then $\delta(XYZ) = -\min(\Psi_Z(u) - \langle u, XYZ \rangle)$, where the minimum is taken over all unit vectors u and where Ψ_Z is the *support function* of Z .

Value

A `data.frame` with N rows and these columns:

<code>within</code>	a logical which is TRUE iff the corresponding row in <code>xyY</code> is inside the optimal color solid for the illuminant. If a point is exactly on the boundary (unlikely), <code>within=TRUE</code> . Explicitly, <code>within = (delta<=0)</code> .
<code>delta</code>	the pseudo-distance δ discussed in Details

The row names of the output value are set equal to the row names of `xyY`.

LabToMunsell

Convert CIE Lab coordinates to Munsell HVC

Description

LabToMunsell Converts CIE Lab coordinates to Munsell HVC, by interpolating over the extrapolated Munsell renotation data

Usage

```
LabToMunsell( Lab, white='D65', adapt='Bradford', ... )
```

Arguments

Lab	CIE Lab coordinates. An Nx3 matrix, or a vector that can be converted to such a matrix. Each row of the matrix has Lab.
white	XYZ for the source white - a numeric 3-vector with scaling irrelevant. white can also be a numeric 2-vector; which is interpreted as xy chromaticity and converted to XYZ with Y=100. white can also be the name of any standard illuminant recognized by <code>spacesXYZ::standardXYZ()</code> which is scaled so that Y=100. The default 'D65' is converted to <code>c(95.047, 100, 108.883)</code> .
adapt	method for chromatic adaptation, see <code>spacesXYZ::CAT()</code> for valid values. Also see Details .
...	other parameters passed to <code>XYZtoMunsell()</code>

Details

The conversion is done in these steps.

- Lab → XYZ using `spacesXYZ::XYZfromLab()` with the given white.
- XYZ is then adapted from the given white to Illuminant C using the given adapt method.
- XYZ → HVC using `XYZtoMunsell()`.

Value

An Nx3 matrix with the Munsell HVC coordinates in each row. The rownames are set to those of Lab.

Note

The case of the letter 't' in the function name was recently changed from lower to upper. The function LabtoMunsell() is equivalent but deprecated and provided for a limited time.

LuvToMunsell

Convert CIE Luv coordinates to Munsell HVC

Description

LuvToMunsell Converts CIE Luv coordinates to Munsell HVC, by interpolating over the extrapolated Munsell renotation data

Usage

```
LuvToMunsell( Luv, white='D65', adapt='Bradford', ... )
```

Arguments

Luv	CIE Luv coordinates An Nx3 matrix, or a vector that can be converted to such a matrix. Each row of the matrix has Luv.
white	XYZ for the source white - a numeric 3-vector with scaling irrelevant. white can also be a numeric 2-vector; which is interpreted as xy chromaticity and converted to XYZ with Y=100. white can also be the name of any standard illuminant recognized by spacesXYZ::standardXYZ() which is scaled so that Y=100. The default 'D65' is converted to c(95.047, 100, 108.883).
adapt	method for chromatic adaptation, see Details
...	other parameters passed to XYZtoMunsell()

Details

The conversion is done in these steps:

- Luv \rightarrow XYZ using `spacesXYZ::XYZfromLuv()` with the given white.
- XYZ is then adapted from the given white to Illuminant C using the given chromatic adaptation method, see `spacesXYZ::CAT()`.
- XYZ \rightarrow HVC using `XYZtoMunsell()`

Value

An Nx3 matrix with the Munsell HVC coordinates in each row. The rownames are set to those of Luv.

Note

The case of the letter 't' in the function name was recently changed from lower to upper. The function `LuvtoMunsell()` is equivalent but deprecated and provided for a limited time.

Munsell2xy

The Munsell HVC to xy 3D Lookup Table

Description

This is the discrete data for the Munsell Renotation System, which is often considered to be the most perceptually uniform color atlas. It was created by the NBS and OSA from "3,000,000 color judgments" by 40 observers.

Format

A data frame with 4995 observations of the following 6 variables.

- H the Munsell Hue. Each H is a multiple of 2.5 and in the interval (0,100].
- V the Munsell Value. Each V is an integer from 1 to 10, or one of 0.2, 0.4, 0.6, 0.8
- C the Munsell Chroma. Each C is a positive even integer.
- x the x chromaticity coordinate, for Illuminant C.
- y the y chromaticity coordinate, for Illuminant C.
- real a logical value. If TRUE then x,y were published, otherwise they have been extrapolated.

Note that the luminance factor Y is **not** here, since Y is a simple function of V, see [YfromV\(\)](#).

Details

All the (x,y) data here comes from the file `all.dat` downloaded from Rochester Institute of Technology, see **Source**. The file `real.dat` is a subset, and contains the (x,y) published in *Newhall, et. al. (1943)*. These rows have `real=TRUE` and are only for $\text{Value} \geq 1$. There are 2734 of these.

Similarly, for $\text{Value} < 1$ (very dark colors), (x,y) data from the paper *Judd et. al. (1956)* also have `real=TRUE`. There are 355 of these.

So `all.dat` has 4995 colors, of which $2734+355=3089$ are "real" colors, and the remaining 1906 are extrapolated. I am confident that the extrapolation was done by *Schleter et. al. (1958)* at the NBS, and put online by the Rochester Institute of Technology. For more details, and the abstract of the 1958 article, see the **munsellinterpol User Guide**.

Note

For the purpose of this package, I have found that the extrapolated (x,y) for $V \geq 1$ work well. But for $V < 1$ they did not work so well, and I was able to get better results with my own extrapolation. Moreover, to get reliable results in this package for high Chroma, it was necessary to extrapolate past the data in `all.dat`.

```

```
HueStringFromNumber( Hue, format='g', digits=2 )
```

Arguments

HVC	a numeric Nx3 matrix or a vector that can be converted to such a matrix. Each row has an HVC vector, where H is Hue Number, and V and C are the standard Munsell Value and Chroma. The Hue is automatically wrapped to the interval (0,100].
Hue	a numeric vector of Hue Numbers, which are automatically wrapped to the interval (0,100].
format	determines the meaning of the argument <code>digits</code> , and usually equal to 'g' or 'f' though other options are available, see formatC() for details. When <code>format='f'</code> trailing 0s might be displayed.
digits	when <code>format='g'</code> the number of significant digits, and when <code>format='f'</code> the number of digits displayed after the decimal point. Both <code>format</code> and <code>digits</code> are passed as arguments to formatC() .

Value

Both functions return a character vector of length N. `MunsellNameFromHVC()` returns the full notation. `HueStringFromNumber()` returns just initial the hue part; which is useful for labeling plots.

Note

If `format='f'`, then Chroma is first *rounded* to the given digits. Chromas close to 0 may then become 0 and be displayed as a neutral, see **Examples**.

The width argument of `formatC()` is always set to 1, to suppress leading spaces.

```

MunsellSpecToColorlabFormat

Convert Munsell Specification to Colorlab Format

Description

Convert Munsell Specification to Colorlab Format

Usage

```
MunsellSpecToColorlabFormat( MunsellSpec )
```

Arguments

MunsellSpec a numeric Nx3 matrix, or a vector that can be converted to such a matrix, by row. Each row of the matrix contains an HVC vector. H is automatically wrapped to the interval (0,100].
MunsellSpec can also be a character vector with Munsell Notation; which is converted to an Nx3 matrix using `HVCfromMunsellName()`.

Details

Colorlab Munsell format uses 4 numbers.

1. Hue Step, in the interval (0,10], or 0 for neutrals. In Colorlab documentation it is called the *hue shade*. It is also the Hue Number H mod 10 (unless H is an exact multiple of 10).
2. Munsell Value, in the interval [0,10]
3. Munsell Chroma, non-negative
4. Hue Index, an integer from 1 to 10, or 0 for neutrals. This index defines the *principal hue*, see **Details**.

Value

an Nx4 matrix, with rows as described in **Details**. Value and Chroma are simply copied unchanged. The complex part is conversion of Hue Number to Colorlab Hue Step and Hue Index. If Chroma is 0, both the Hue Step and Hue Index are set to 0. Invalid input values are converted to NAs. If the input is a character vector, the rownames of the returned matrix are set to that vector.

Note

The Colorlab format is closer to the *Munsell Book of Color (1929)* than HVC. In the book the hue circle is divided into 10 *principal hues* - 5 simple and 5 compound. The 10 hue labels are: **R, YR, Y, GY G, BG, B, PB, P** (simple are 1 letter and compound are 2 letters). In Colorlab these labels are replaced by the Hue Index. **WARNING:** In the Munsell System, see *Cleland*, there is a different Hue Index - **R** is 1, **YR** is 2, ..., **P** is 10. The Colorlab index has a different origin, and goes around the circle in a different direction !

Each one of these major hues corresponds to an arc on the circle, with a 10-point hue scale. The midpoint of the arc has hue step = 5. Fortunately this 10-point hue scale is exactly the same as the Colorlab Hue Step.

MunsellToLab

Convert a Munsell specification to CIE Lab coordinates

Description

MunsellToLab Converts a Munsell specification to CIE Lab coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToLab( MunsellSpec, white='D65', adapt='Bradford', ... )
```

Arguments

MunsellSpec	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. MunsellSpec can also be a character vector with Munsell Notations, which is converted to an Nx3 matrix HVC using HVCfromMunsellName()
white	XYZ for the source white - a numeric 3-vector with scaling irrelevant. white can also be a numeric 2-vector; which is interpreted as xy chromaticity and converted to XYZ with Y=100. white can also be the name of any standard illuminant recognized by spacesXYZ::standardXYZ() which is scaled so that Y=100. The default 'D65' is converted to c(95.047,100,108.883).
adapt	method for chromatic adaptation, see spacesXYZ::CAT() for valid values. Also see Details .
...	other parameters passed to MunsellToXYZ()

Details

The conversion is done in these steps:

- HVC → XYZ using [MunsellToXYZ\(\)](#)
- XYZ is adapted from Illuminant C to the given white using [spacesXYZ::adaptXYZ\(\)](#) and the given chromatic adaptation method
- XYZ → Lab using [spacesXYZ::LabfromXYZ\(\)](#) with the given white

Value

An Nx3 matrix with the Lab coordinates in each row. The rownames of Lab are copied from the input HVC matrix, unless the rownames are NULL and then the output rownames are the Munsell notations for HVC.

MunsellToLuv

Convert a Munsell specification to CIE Luv coordinates

Description

MunsellToLuv Converts a Munsell specification to CIE Luv coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToLuv( MunsellSpec, white='D65', adapt='Bradford', ... )
```

Arguments

MunsellSpec a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row.
MunsellSpec can also be a character vector with Munsell Notations, which is converted to an Nx3 matrix using [HVCfromMunsellName\(\)](#)

white	XYZ for the source white - a numeric 3-vector with scaling irrelevant. white can also be a numeric 2-vector; which is interpreted as xy chromaticity and converted to XYZ with Y=100. white can also be the name of any standard illuminant recognized by <code>spacesXYZ::standardXYZ()</code> which is scaled so that Y=100. The default 'D65' is converted to <code>c(95.047, 100, 108.883)</code> .
adapt	method for chromatic adaptation, see <code>spacesXYZ::CAT()</code> for valid values. Also see Details .
...	other parameters passed to <code>MunsellToXYZ()</code>

Details

The conversion is done in these steps:

- HVC → XYZ using `MunsellToXYZ()`
- XYZ is adapted from Illuminant C to the given white using `spacesXYZ::adaptXYZ()` with the given chromatic adaptation method
- XYZ → Luv using `spacesXYZ::LuvfromXYZ()` with the given white

Value

An Nx3 matrix with the Luv coordinates in each row. The rownames of Luv are copied from the input HVC matrix, unless the rownames are NULL and then the output rownames are the Munsell notations for HVC.

MunsellToRGB	<i>Convert a Munsell specification to RGB coordinates</i>
--------------	---

Description

MunsellToRGB Converts a Munsell specification to RGB coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToRGB( MunsellSpec, space='sRGB', which='scene', maxSignal=255,
              adapt='Bradford', ... )
```

Arguments

MunsellSpec	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. MunsellSpec can also be a character vector with Munsell Notations, which is converted to an Nx3 matrix using HVCfromMunsellName() .
space	the name of an installed RGB space. Spaces 'sRGB' and 'AdobeRGB' are pre-installed, and others can be installed with spacesRGB::installRGB() .
which	either 'scene' or 'display'; passed to spacesRGB::RGBfromXYZ()
maxSignal	maximum of the non-linear signal RGB; Other popular values are 1, 100, 1023, and 65535
adapt	method for chromatic adaptation, see spacesXYZ::CAT() for valid values. Also see Details .
...	other parameters passed to MunsellToxyY()

Details

The conversion is done with these steps:

- HVC \rightarrow xyY using [MunsellToxyY\(\)](#) with ... This xyY is for Illuminant C.
- xyY \rightarrow XYZ using [spacesXYZ::XYZfromxyY\(\)](#)
- XYZ is adapted from Illuminant C to the white-point (with which) of the RGB space, using [spacesXYZ::adaptXYZ\(\)](#), with the given chromatic adaptation method adapt
- XYZ \rightarrow RGB using [spacesRGB::RGBfromXYZ\(\)](#) with the given space, which, and maxSignal

Value

a data.frame with these columns:

SAMPLE_NAME	a character N-vector equal to the original MunsellSpec if that was a character vector. Or the Munsell notation string converted from the input matrix HVC.
-------------	--

xyY	an Nx3 matrix with xyY values in the rows, that are adapted to Illuminant C. This is an intermediate result that is sometimes useful, e.g. it can be passed to IsWithinMacAdamLimits() . The rownames of xyY are copied from those of HVC, unless the rownames of HVC are NULL when they are set to SAMPLE_NAME.
RGB	an Nx3 matrix with non-linear RGB signal values in the rows. All values are clamped to the appropriate cube, e.g. $[0, 255]^3$. The rownames of RGB are copied from those of xyY.
OutOfGamut	logical vector, TRUE means the result was out of gamut (the cube) before clamping it

In case of error, it returns NULL.

## 2      N 3/ 0.3101000 0.3163000 6.3911778 73.01793 73.01793 73.01793   FALSE
```

MunsellToRGB

Convert a Munsell specification to sRGB coordinates

Description

MunsellToRGB Converts a Munsell specification to non-linear sRGB coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToRGB( MunsellSpec, maxSignal=255, ... )
```

Arguments

MunsellSpec	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. MunsellSpec can also be a character N-vector with Munsell notations, which is converted to an Nx3 matrix using <code>HVCfromMunsellName()</code> .
maxSignal	maximum of signal sRGB; Other popular values are 1, 100, 1023, and 65535
...	other parameters passed to <code>MunsellToxyY()</code>

Details

The conversion is done in these steps.

- HVC \rightarrow xyY using `MunsellToxyY()` and the given ... This xyY is for Illuminant C.
- xyY \rightarrow XYZ using `spacesXYZ::XYZfromxyY()`
- XYZ is adapted from Illuminant C to Illuminant D65 (from the sRGB standard) using `spacesXYZ::adaptXYZ()` and the *Bradford* chromatic adaptation method
- XYZ \rightarrow sRGB using `spacesRGB::RGBfromXYZ()` with the given maxSignal

Value

a data.frame with these columns:

SAMPLE_NAME	the original MunsellSpec if that was a character vector. Or the Munsell notation string converted from the input matrix HVC.
xyY	an Nx3 matrix with xyY values in the rows, that are adapted to Illuminant C. This is an intermediate result that is sometimes useful, e.g. it can be passed to <code>IsWithinMacAdamLimits()</code> . The rownames of xyY are copied from those of HVC, unless the rownames of HVC are NULL when they are set to SAMPLE_NAME.
RGB	an Nx3 matrix with non-linear signal sRGB values in the rows. All values are clamped to the appropriate cube, e.g. $[0, 255]^3$. The rownames of RGB are copied from those of xyY.
OutOfGamut	logical vector, TRUE means the RGB result was out of gamut (the cube) before clamping it

Note

The more general function `MunsellToRGB()` also performs this conversion. The main reason to use `MunsellToRGB()` is that it takes a little less time, since the CAT (using the *Bradford* method) is precomputed during `base:::onLoad()`.

```

MunsellToxyY	<i>Convert Munsell HVC to xyY coordinates</i>
--------------	---

Description

MunsellToxyY Converts Munsell HVC to xyY coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToxyY( MunsellSpec, xyC='NBS', hcinterp='bicubic', vinterp='cubic',
              YfromV='ASTM', warn=TRUE )
```

Arguments

MunsellSpec	a numeric Nx3 matrix or a vector that can be converted to such a matrix. Each row has Munsell HVC, where H is Hue Number, and V and C are the standard Munsell Value and Chroma. The Hue is automatically wrapped to the interval (0,100]. MunsellSpec can also be a character N-vector with standard Munsell notation; it is converted to an Nx3 matrix.
xyC	a numeric 2-vector with xy chromaticity of Illuminant C. It can also be one of the strings in the first column of this table; it is then replaced by the corresponding xy in the second column.

	xy white point	reference
'NBS'	c(0.3101,0.3163)	Kelly, et. al. [RP1549] (1943). Rheinboldt et al. (1960)
'JOSA'	c(0.31012,0.31631)	Judd, Deane B. (1933)
'NTSC'	c(0.310,0.316)	NTSC (1953)
'CIE'	c(0.31006,0.31616)	CIE:15 2004

The default 'NBS' is probably what is intended by *Newhall et. al.* although no xy for C appears in that paper. This is the C used in the first computer program for conversion: *Rheinboldt et al. (1960)*. The other options are provided so that a neutral Munsell chip has the xy that the user expects. Alternative values of xyC should not be *too far* from the above. If hcinterp is 'bicubic', this

	parameter only affects chips with Chroma < 4 (except Chroma=2). If <code>hcinterp</code> is 'bilinear', this parameter only affects chips with Chroma < 2.
<code>hcinterp</code>	either 'bicubic' or 'bilinear' (partial matching enabled). In the bicubic case, for a general input point, the output value is interpolated using a 4x4 subgrid of the lookup table, and the interpolation function is class C^1 (except at the neutrals). In the bilinear case, the interpolation uses a 2x2 subgrid, and the function is class C^0 .
<code>vinterp</code>	either 'cubic' or 'linear' (partial matching enabled). In the cubic case, for a general input point, the output value is interpolated using 4 planes of constant Value, and the interpolation function is class C^1 . In the linear case, the interpolation uses 2 planes and the function is class C^0 .
<code>YfromV</code>	passed as the parameter which to the function <code>YfromV()</code> . See <code>YfromV()</code> for details. Option 'MGO' is not allowed because then $Y > 100$ when $V = 10$.
<code>warn</code>	if a chip cannot be mapped (usually because the Chroma is too large), its x and y are set to NA in the returned data.frame. Just before returning, if any rows have NA, and this argument is TRUE, then a warning is logged.

Details

In case `hcinterp='bicubic'` or `vinterp='cubic'` a Catmull-Rom spline is used; see the article *Cubic Hermite spline*. This spline has the nice property that it is *local* and requires at most 4 points. And if the knot spacing is uniform: 1) the resulting spline is C^1 , 2) if the knots are on a line, the interpolated points are on the line too.

Value

a data.frame with these columns:

<code>SAMPLE_NAME</code>	the original MunsellSpec if that was a character vector. Or the Munsell notation string converted from the input matrix HVC.
<code>HVC</code>	the input Nx3 matrix, or the HVC matrix converted from the input Munsell notation
<code>xyY</code>	the computed output matrix, with CIE xyY coordinates of MunsellSpec illuminated by Illuminant C. In case of error, x and y are set to NA. The rownames of xyY are set to those of HVC, unless they are NULL when they are set to <code>SAMPLE_NAME</code> .

Warning

Even when `vinterp='cubic'` the function $HVC \rightarrow xyY$ is not C^1 on the plane $V=1$. This is because of a change in Value spacing: when $V \geq 1$ the Value spacing is 1, but when $V \leq 1$ the Value spacing is 0.2.

Note

When making plots in planes of constant Value, option `hcinterp='bicubic'` makes fairly smooth ovals, and `hcinterp='bilinear'` makes polygons. The ovals are smooth even when `vinterp='linear'`, but the function is not class C^1 at the planes of integer Value. To get a fully C^1 function (except at the neutrals and on the plane $V=1$), `hcinterp` and `vinterp` must be set to the defaults.

`MunsellToXYZ`*Convert a Munsell specification to CIE XYZ coordinates*

Description

`MunsellToXYZ` Converts a Munsell specification to XYZ coordinates, by interpolating over the extrapolated Munsell renotation data

Usage

```
MunsellToXYZ( MunsellSpec, ... )
```

Arguments

<code>MunsellSpec</code>	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. MunsellSpec can also be a character vector with Munsell Notations, which is converted to an Nx3 matrix using <code>HVCfromMunsellName()</code> .
<code>...</code>	other parameters passed to <code>MunsellToxyY()</code>

Details

The conversion is done in these steps:

- HVC → xyY using `MunsellToxyY()` and `...`. This xyY is for Illuminant C.
- xyY → XYZ using `spacesXYZ::XYZfromxyY()`

Value

an Nx3 matrix with XYZ values in the rows. The rownames of XYZ are copied from the input HVC matrix, unless the rownames are NULL and then the output rownames are the Munsell notations for HVC. Note that these XYZ values are for viewing under Illuminant C, with Y=100. There is no chromatic adaptation.

NickersonColorDifference

Calculate the Nickerson Color Difference between two Colors

Description

Calculate the Nickerson Color Difference between two colors, given in Munsell HVC; see *Nickerson*.

Usage

```
NickersonColorDifference( HVC0, HVC1, symmetric=TRUE )
```

Arguments

HVC0	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. HVC0 can also be a numeric 3-vector with a single HVC, and it is then replicated to match the size of HVC1. HVC0 can also be a character N-vector with Munsell Notations, which is converted to an Nx3 matrix using HVCfromMunsellName() .
HVC1	a numeric Nx3 matrix with HVC values in the rows, or a vector that can be converted to such a matrix, by row. HVC1 can also be a numeric 3-vector with a single HVC, and it is then replicated to match the size of HVC0. HVC1 can also be a character N-vector with Munsell Notations, which is converted to an Nx3 matrix using HVCfromMunsellName() .
symmetric	if FALSE then use the original Nickerson difference formula, and if TRUE then use a symmetrized version; see Details .

Details

If $HVC0=H_0, V_0, C_0$ and If $HVC1=H_1, V_1, C_1$ then the original Nickerson formula is:

$$NCD(HVC0, HVC1) = 0.4C_0\Delta H + 6\Delta V + 3\Delta C$$

where $\Delta H = |H_0 - H_1|$ (on the circle), $\Delta V = |V_0 - V_1|$ and $\Delta C = |C_0 - C_1|$. Unfortunately, if HVC0 and HVC1 are swapped, the color difference is different. The first color is considered to be the *reference color* and the second one is the *test color*. The difference is not symmetric.

Another problem is that the difference is not continuous when the second color is a neutral gray, for rectangular coordinates on a plane of constant V.

Both of these problems are fixed with a slightly modified formula:

$$NCD(HVC0, HVC1) = 0.4 \min(C_0, C_1)\Delta H + 6\Delta V + 3\Delta C$$

For the first formula set `symmetric=FALSE` and for the second formula set `symmetric=TRUE`.

Value

A numeric N-vector with the pairwise differences, i.e. between row i of HVC0 and row i of HVC1.

plotLociHC

Plot Curves of Constant Munsell Hue and Chroma

Description

Plot Curves of Constant Munsell Hue and Chroma

Usage

```
plotLociHC( value=5, hue=seq(2.5,100,by=2.5), chroma='auto', coords='xy',
            main="Value %g/", est=FALSE, ... )
```

Arguments

value	a Munsell value for which the plot is created. It must be in the interval (0,10]. value can also be a numeric vector of such numbers, and then a separate plot is made for each element of the vector.
hue	a numeric vector for which curves of constant Hue are plotted. Each of these radial curves starts at Munsell Chroma = $\min(\text{chroma}, 1)$ and extends to $\max(\text{chroma})$. hue can also be a character vector, which is then converted to a numeric vector using HueNumberFromString() .
chroma	a numeric vector for which ovoids of constant Chroma are plotted. Each of these ovoids is closed; i.e. goes full circle from Hue=0 to Hue=100. If chroma='auto' then a vector is chosen appropriate for the current value.
coords	either 'xy' or 'ab'. If coords='xy' then the plots are in the standard xy chromaticity plane. If coords='ab' then the plots are in the ab chrominance plane, from Lab. Even when it is 'ab', the interpolation of loci takes place in 'xy' before transformation to Lab.

main	a string used to set the main title of the plot. The optional placeholder '%g' is replaced by the current value.
est	if TRUE, initial estimates for the iteration used in <code>xyYtoMunsell()</code> are plotted
...	other arguments passed to the function <code>MunsellToxyY()</code> . This includes <code>hcinterp</code> , <code>vinterp</code> , and <code>xyC</code> . However <code>warn=FALSE</code> is forced.

Details

The plot limits (`xlim` and `ylim`) are set to include all points where the Hue radials intersect the Chroma ovoids, plus the white point.

If value is one of {0.2,0.4,0.6,0.8,1,2,3,4,5,6,7,8,9,10} then published points from `real.dat` are plotted with filled black points (real points), and extrapolated points from `all.dat` are drawn with open circles (unreal points).

Value

TRUE for success and FALSE for failure.

Note

The option `hcinterp='bicubic'` makes fairly smooth ovoids, and `hcinterp='bilinear'` makes 40-sided polygons (when `coords='xy'`). Compare with the plots in *Newhall et. al. (1943)*, *Judd, et. al. (1956)*, and *Judd, et. al. (1975)* p. 263.

plotPatchesH

Plot Colored Patches for a fixed Munsell Hue

Description

This plot simulates a page from the Munsell Book of Color. The colors are best viewed on a display calibrated for the RGB space given as the second argument.

Usage

```
plotPatchesH( hue, space='sRGB', adapt='Bradford', background='gray50',
              main="Hue %s (H=%g) [%s adapt=%s]", ... )
```

Arguments

hue	a Munsell hue for which the plot is created. It is automatically wrapped to the interval (0,100]. It does not have to be a multiple of 2.5. hue can also be a numeric vector of such numbers, and then a separate plot is made for each element of the vector. hue can also be a character vector of Hue Names, which is then converted to a numeric vector using HueNumberFromString() .
space	the name of an installed RGB space. Spaces 'sRGB' and 'AdobeRGB' are pre-installed, and others can be installed using spacesRGB::installRGB()
adapt	method used to adapt xyY for Illuminant C to xyY for Illuminant D65. It is passed to MunsellToRGB() .
background	background color for the plot. It is passed to <code>par()</code> as argument <code>bg</code> .
main	a string used to set the main title of the plot. The optional placeholder '%s' is replaced by the Hue Name, '%g' is replaced by the Hue Number, the next '%s' is replaced by space, and the last '%s' is replaced by adapt.
...	other arguments passed to the function MunsellToRGB() . This includes <code>hcinterp</code> , <code>vinterp</code> , and <code>xyC</code> .

Details

The discrete Values are always the same: integers from 0 to 10. And so the plotting parameter `ylim=c(0,11)`.

The discrete Chromas are contiguous even integers depending on the Hue, and determined as follows. For the closest discrete Hue in `real.dat`, the patches in `real.dat` are transformed to xyY using simple lookup. These are then tested against the MacAdam Limits for Illuminant C using [IsWithinMacAdamLimits\(\)](#). The patches outside the limits are discarded, and the maximum Chroma of the remaining patches, which is always an even integer, determines `xlim`.

Patches inside the MacAdam Limits can still be outside the RGB cube. Patches inside the cube are drawn in the usual way, and those outside are drawn in outline only, and with the clamped RGB coordinates printed inside.

Value

TRUE for success and FALSE for failure.

RGBtoMunsell*Convert RGB coordinates to Munsell HVC*

Description

RGBtoMunsell Converts RGB coordinates to Munsell HVC, by interpolating over the extrapolated Munsell renotation data

Usage

```
RGBtoMunsell( RGB, space='sRGB', which='scene', maxSignal=255, adapt='Bradford', ... )
```

Arguments

RGB	a numeric Nx3 matrix with RGB coordinates in the rows, or a vector that can be converted to such a matrix, by row. These are non-linear display values, but they are not required to be integers.
space	the name of an installed RGB space. Spaces 'sRGB' and 'AdobeRGB' are pre-installed, and others can be installed using spacesRGB::installRGB() .
which	either 'scene' or 'display'; passed to spacesRGB::XYZfromRGB()
maxSignal	maximum value of signal RGB. Other popular values are 1, 100, 1023, and 65535. Even when 1, they are still taken to be non-linear signal values.
adapt	method for chromatic adaptation, see spacesXYZ::CAT() for valid values. Also see Details .
...	other parameters passed to XYZtoMunsell()

Details

The conversion is done in these steps:

- RGB → XYZ using [spacesRGB::XYZfromRGB\(\)](#) with the given space, which, and maxSignal
- XYZ is adapted from the white-point (with which) of space to Illuminant C, using [spacesXYZ::adaptXYZ\(\)](#), with the given chromatic adaptation method adapt
- XYZ → HVC using [XYZtoMunsell\(\)](#) with ...

Value

a numeric Nx3 matrix with HVC coordinates in the rows. The rownames are copied from input RGB to output HVC, unless the rownames are NULL when they are set to the Munsell notations for HVC.

In case of error, it returns NULL.

sRGBtoMunsell

Convert sRGB coordinates to Munsell HVC

Description

Converts non-linear sRGB coordinates to Munsell HVC, by interpolating over the extrapolated Munsell renotation data

Usage

```
sRGBtoMunsell( sRGB, maxSignal=255, ... )
```

Arguments

sRGB	a numeric Nx3 matrix with signal sRGB coordinates in the rows, or a vector that can be converted to such a matrix, by row. These are non-linear signal values, but they are not required to be integers.
maxSignal	maximum value of signal sRGB. Other popular values are 1, 100, 1023, and 65535. Even when 1, they are still taken to be non-linear signal values.
...	other parameters passed to XYZtoMunsell()

Details

The conversion is done in these steps:

- sRGB → XYZ using [spacesXYZ::XYZfromRGB\(\)](#) with the given maxSignal
- XYZ is adapted from Illuminant D65 (from the sRGB standard) to Illuminant C, using [spacesXYZ::adaptXYZ\(\)](#) with the *Bradford* chromatic adaptation method
- XYZ → HVC using [XYZtoMunsell\(\)](#) and the given ...

Value

a numeric Nx3 matrix with HVC coordinates in the rows. The rownames are copied from input to output, unless the rownames are NULL when they are set to the Munsell notations for HVC. In case of error, it returns NULL.

Note

The more general function [RGBtoMunsell\(\)](#) also performs this conversion. This function has the advantage that it takes a little less time, since the CAT (using the *Bradford* method) is precomputed during [base:::onLoad\(\)](#). But it has the disadvantage that the chromatic adaptation method cannot be changed.

VandY

*Convert Munsell Value V to Luminance Factor Y, and back again***Description**

Convert non-linear Munsell Value V to linear Luminance Factor Y, and back again

Usage

```
YfromV( V, which='ASTM' )
VfromY( Y, which='ASTM' )
```

Arguments

V a numeric vector with elements in the interval [0,10]
Y a numeric vector with elements in the interval [0,100]
which one of the strings in the first column of this table

	reference
'ASTM'	ASTM D-1535 (2008)
'OSA'	Newhall, et. al. (1943)
'MgO'	Newhall, et. al. (1943)
'Munsell'	Munsell, et. al. (1933)
'Priest'	Priest, et. al. (1920)

Partial matching is enabled, and it is case insensitive.

Details

'Priest' is the earliest (1920) transfer function in this package. It is implemented as:

$$V = \sqrt{Y} \quad \text{and} \quad Y = V^2$$

One readily checks that when V=10, Y=100, and vice-versa. This transfer function has been implemented in colorimeters, using analog electric circuits. It is used in Hunter Lab - the precursor of CIE Lab.

'Munsell' is the next (1933) transfer function, and was proposed by Munsell's son (Alexander Ector Orr Munsell) and co-workers. It is implemented as:

$$V = \text{sqrt}(1.474 * Y - 0.00474 * Y^2)$$

$$Y = 50 * ((1474 - \text{sqrt}(1474^2 - 4 * 4740 * V^2))/474)$$

One readily checks that when V=10, Y=100, and vice-versa. The luminance factor Y is *absolute*, AKA *relative to the perfect reflecting diffuser*.

'Priest' and 'Munsell' are included in this package for historical interest only.

The remaining three define Y as a quintic polynomial in V.

The next one historically - 'MgO' - is implemented as:

$$Y = (((((8404 * V - 210090) * V + 2395100) * V - 2311100) * V + 10000000) * V)/10000000$$

One readily checks that when V=10, Y=102.568. This Y is larger than 100, because the authors decided to make Y relative to a clean surface of MgO, instead of the perfect reflecting diffuser. In their words:

- It should be noted that the reflectances indicated are not absolute but relative to magnesium oxide; whereas the maximum at value 10/ was formerly 100 percent, it is now 102.57. Use of this relation facilitates results and also avoids the somewhat dubious conversion to absolute scale, by permitting Y determinations with a MgO standard to be converted directly to Munsell value.

Nowadays, the perfect reflecting diffuser is preferred over MgO. For users who would like to modify this quintic as little as possible, with the perfect reflecting diffuser in mind (going back to 'MUNSELL'), I offer 'OSA', which is given by this quintic of my own design

$$Y = (((((8404 * V - 210090) * V + 2395100) * V - 2311100) * V + 10000000) * V)/10256800$$

ASTM had a similar modification in mind, but did it a little differently by scaling each coefficient. 'ASTM' is given by this quintic:

$$Y = (((((81939 * V - 2048400) * V + 23352000) * V - 22533000) * V + 119140000) * V)/1.e8$$

One readily checks that when V=10, Y=100 exactly (for both 'OSA' and 'ASTM').

The inverses - from Y to V - of all 3 quintics are implemented as 3 `splinefun()`s at a large number (about 300) of points. These inverses are both fast and accurate. The round-trip $Y \rightarrow V \rightarrow Y$ is accurate to 7 digits after the decimal. The round-trip $V \rightarrow Y \rightarrow V$ is accurate to 8 digits after the decimal.

Value

a numeric vector the same length as the input

Note

The quintic functions 'ASTM' and 'OSA' are very close. They agree at the endpoints 0 and 10 exactly, and the largest difference is near V=6.767 where they differ by about 0.0007.

xyYtoMunsell

Convert xyY coordinates to Munsell HVC

Description

xyYtoMunsell Convert xyY coordinates to Munsell HVC, by interpolating over the extrapolated Munsell renotation data.

HVC \rightarrow xyY is the forward direction, and xyY \rightarrow HVC is the inverse direction. This inversion requires requires root-finding, which is done using [rootSolve::multiroot\(\)](#).

Usage

```
xyYtoMunsell( xyY, xyC='NBS', hcinterp='bicubic', vinterp='cubic',
              VfromY='ASTM', rtol=1.e-8, atol=1.e-6, warn=TRUE, perf=FALSE )
```

Arguments

xyY	a numeric Nx3 matrix with CIE xyY coordinates in the rows, or a vector that can be converted to such a matrix, by row. These are for viewing in an environment with Illuminant C, with Y=100.
xyC	a numeric 2-vector with xy chromaticity of Illuminant C. It can also be one of the strings given in MunsellToxyY() .
hcinterp	either 'bicubic' or 'bilinear' (partial matching enabled). See MunsellToxyY() for details.
vinterp	either 'cubic' or 'linear' (partial matching enabled). See MunsellToxyY() for details.
VfromY	passed as the parameter which to the function VfromY() . See VfromY() for details. Option 'MGO' is not allowed because then $Y > 100$ when $V = 10$.
rtol	relative tolerance passed to rootSolve::multiroot()
atol	absolute tolerance passed to rootSolve::multiroot()
warn	if an xyY cannot be mapped (usually because the root finder has wandered afar), its H and V are set to NA in the returned data.frame. Just before returning, if any rows in HVC have an NA, and <code>warn == TRUE</code> , then a warning is logged.
perf	if perf is TRUE, then extra performance related metrics are appended to the returned data.frame, see Value .

Details

See [MunsellToxyY\(\)](#) and the **User Guide - Appendix C**.

Value

a data.frame with N rows and these columns:

xyY	The input xyY
HVC	the computed HVC. H is automatically wrapped to (0,100]. In case of failure, H and C are set to NA. The rownames of HVC are set to those of xyY, unless they are NULL when they are set to SAMPLE_NAME.
SAMPLE_NAME	the Munsell notation for HVC, a character vector

If perf is TRUE then there are these additional columns:

time.elapsed	elapsed time in seconds. If available, the function <code>microbenchmark::get_nanotime()</code> is used.
iterations	the number of iterations of <code>rootSolve::multiroot()</code>
evalations	the number of forward (HVC \rightarrow xyY) function evaluations
estim.precis	the estimated precision from <code>rootSolve::multiroot()</code> . This is in the HC plane for the Munsell Value computed from Y.

Warning

Even when `vinterp='cubic'` the function $xyY \rightarrow HVC$ is not C^1 on the plane $V=1$. This is because of a change in Value spacing: when $V \geq 1$ the Value spacing is 1, but when $V \leq 1$ the Value spacing is 0.2.

`XYZtoMunsell`*Convert XYZ coordinates to Munsell HVC*

Description

`XYZtoMunsell` Convert XYZ coordinates to Munsell HVC, by interpolating over the Munsell notation data

Usage

```
XYZtoMunsell( XYZ, ... )
```

Arguments

<code>XYZ</code>	a numeric Nx3 matrix with CIE XYZ coordinates in the rows, or a vector that can be converted to such a matrix, by row. The XYZ are for viewing in an environment with Illuminant C.
<code>...</code>	other parameters passed to <code>xyYtoMunsell()</code>

Details

the function calls `XYZ2xyY()` and `xyYtoMunsell()`.

The conversion is done in these steps:

- `XYZ` → `xyY` using `spacesXYZ::xyYfromXYZ()`
- `xyY` → HVC using `xyYtoMunsell()` and ...

Value

an Nx3 matrix with Munsell HVC in the rows. The rownames are copied from input to output, unless the rownames are NULL when they are set to the Munsell notations for HVC. In case of error, it returns NULL.
