

Package ‘rvMF’

March 27, 2024

Title Fast Generation of von Mises-Fisher Distributed Pseudo-Random Vectors

Version 0.1.0

Description Generates pseudo-random vectors that follow an arbitrary von Mises-Fisher distribution on a sphere. This method is fast and efficient when generating a large number of pseudo-random vectors. Functions to generate random variates and compute density for the distribution of an inner product between von Mises-Fisher random vector and its mean direction are also provided. Details are in Kang and Oh (2024) <[doi:10.1007/s11222-024-10419-3](https://doi.org/10.1007/s11222-024-10419-3)>.

`rvMF`*von Mises–Fisher Distributed Pseudo-Random Vector Generator*

Description

`rvMF()` generates von Mises–Fisher distributed pseudo-random vectors, without resorting to the rejection-based sampling method proposed by Wood (1994). See Kang and Oh (2024) for details. This function partly uses the code from the function `Rfast::rvmf()` and the article Marsaglia et al. (2004).

Usage

```
rvMF(n, mu, k)
```

Arguments

<code>n</code>	number of pseudo-random vectors to generate.
<code>mu</code>	mean direction.
<code>k</code>	concentration parameter. $k \geq 0$.

Value

matrix where each row independently follows the specified von Mises-Fisher distribution. The number of columns equals the length of `mu`, and the number of rows equals `n` for `rvMF`.

vMFangle	<i>Inner Product of von Mises–Fisher Random Vector and Mean Direction</i>
----------	---------------------------------------------------------------------------

Description

These functions provide information about the distribution of an inner product between von Mises–Fisher random vector and its mean direction. Specifically, if X follows a von Mises–Fisher distribution with mean direction μ , the inner product $X'\mu$ will be a random variable following some distribution. See page 170 of Mardia and Jupp (1999). `rvMFangle()` generates random variates using the algorithm proposed in Kang and Oh (2024), and `dvMFangle` gives the density from this distribution. This function partly uses the code from the article Marsaglia et al. (2004).

Usage

```
rvMFangle(n, p, kappa)
```

```
dvMFangle(r, p, kappa)
```

Arguments

n	number of random vectors to generate.
p	dimension of the sphere. i.e., S^{p-1} , $p \geq 2$.
kappa	concentration parameter. $\text{kappa} > 0$. Setting $\text{kappa} = 0$ may cause errors.
r	vector of quantiles. $-1 \leq r \leq 1$.

Value

- `rvMFangle()` returns a vector whose components independently follow the aforementioned distribution. The length of the result is determined by `n` for `rvMFangle()`.
- `dvMFangle()` returns a vector of density function value. The length of the result is determined by the length of `r` for `dvMFangle()`.
